**International Chemistry Olympiad 2021 Japan**

**53rd IChO2021 Japan**

**25th July - 2nd August, 2021**

**<https://www.icho2021.org>**

### General Instruction

- You are allowed to use only pen to write the answer.
- Your calculator must be non-programmable.
- This examination has **9 problems**.
- You can solve the problems in any order.
- You will have **5 hours** to solve all problems.
- You can **begin** working only after the **START** command is given.
- All results must be written in the appropriate answer boxes with pen on the **answer sheets**. Use the back of the question sheets if you need scratch paper. Remember that answers written outside the answer boxes will not be graded.
- Write relevant calculations in the appropriate boxes when necessary. Full marks will be given for correct answers only when your work is shown.
- The invigilator will announce a **30-minute** warning before the **STOP** command.
- You **must stop** working when the **STOP** command is given. Failure to stop writing will lead to the nullification of your examination.
- The official English version of this examination is available on request only for clarification.
- You are not allowed to leave your working place without permission. If you need any assistance (broken calculator, need to visit a restroom, etc), raise your hand and wait until an invigilator arrives.

**GOOD LUCK!**

## Physical Constants and Equations

### Constants

Speed of light in vacuum	$c = 2.99792458 \times 10^8 \text{ m s}^{-1}$
Planck constant	$h = 6.62607015 \times 10^{-34} \text{ J s}$
Elementary charge	$e = 1.602176634 \times 10^{-19} \text{ C}$
Electron mass	$m_e = 9.10938370 \times 10^{-31} \text{ kg}$
Electric constant (permittivity of vacuum)	$\epsilon_0 = 8.85418781 \times 10^{-12} \text{ F m}^{-1}$
Avogadro constant	$N_A = 6.02214076 \times 10^{23} \text{ mol}^{-1}$
Boltzmann constant	$k_B = 1.380649 \times 10^{-23} \text{ J K}^{-1}$
Faraday constant	$F = N_A \times e = 9.64853321233100184 \times 10^4 \text{ C mol}^{-1}$
Gas constant	$R = N_A \times k_B = 8.31446261815324 \text{ J K}^{-1} \text{ mol}^{-1}$ $= 8.2057366081 \times 10^{-2} \text{ L atm K}^{-1} \text{ mol}^{-1}$
Unified atomic mass unit	$u = 1 \text{ Da} = 1.66053907 \times 10^{-27} \text{ kg}$
Standard pressure	$p = 1 \text{ bar} = 10^5 \text{ Pa}$
Atmospheric pressure	$p_{\text{atm}} = 1.01325 \times 10^5 \text{ Pa}$
Zero degree Celsius	$0^\circ\text{C} = 273.15 \text{ K}$
Ångstrom	$1 \text{ \AA} = 10^{-10} \text{ m}$
Picometer	$1 \text{ pm} = 10^{-12} \text{ m}$
Electronvolt	$1 \text{ eV} = 1.602176634 \times 10^{-19} \text{ J}$
Part-per-million	$1 \text{ ppm} = 10^{-6}$
Part-per-billion	$1 \text{ ppb} = 10^{-9}$
Part-per-trillion	$1 \text{ ppt} = 10^{-12}$
pi	$\pi = 3.141592653589793$
The base of the natural logarithm (Euler's number)	$e = 2.718281828459045$

## Equations

The ideal gas law	$PV = nRT$ , where $P$ is the pressure, $V$ is the volume, $n$ is the amount of substance, $T$ is the absolute temperature of ideal gas.
Coulomb's law	$F = k_e \frac{q_1 q_2}{r^2}$ , where $F$ is the electrostatic force, $k_e (\simeq 9.0 \times 10^9 \text{ N m}^2 \text{ C}^{-2})$ is Coulomb's constant, $q_1$ and $q_2$ are the magnitudes of the charges, and $r$ is the distance between the charges.
The first law of thermodynamics	$\Delta U = q + w$ , where $\Delta U$ is the change in the internal energy, $q$ is the heat supplied, $w$ is the work done.
Enthalpy $H$	$H = U + PV$
Entropy based on Boltzmann's principle $S$	$S = k_B \ln W$ , where $W$ is the number of microstates.
The change of entropy $\Delta S$	$\Delta S = \frac{q_{\text{rev}}}{T}$ , where $q_{\text{rev}}$ is the heat for the reversible process.
Gibbs free energy $G$	$G = H - TS$ $\Delta_r G^\circ = -RT \ln K = -zFE^\circ$ , where $K$ is the equilibrium constant, $z$ is the number of electrons, $E^\circ$ is the standard electrode potential.
Reaction quotient $Q$	$\Delta_r G = \Delta_r G^\circ + RT \ln Q$ For a reaction $aA + bB \rightleftharpoons cC + dD$ $Q = \frac{[C]^c [D]^d}{[A]^a [B]^b}$ , where $[A]$ is the concentration of A.

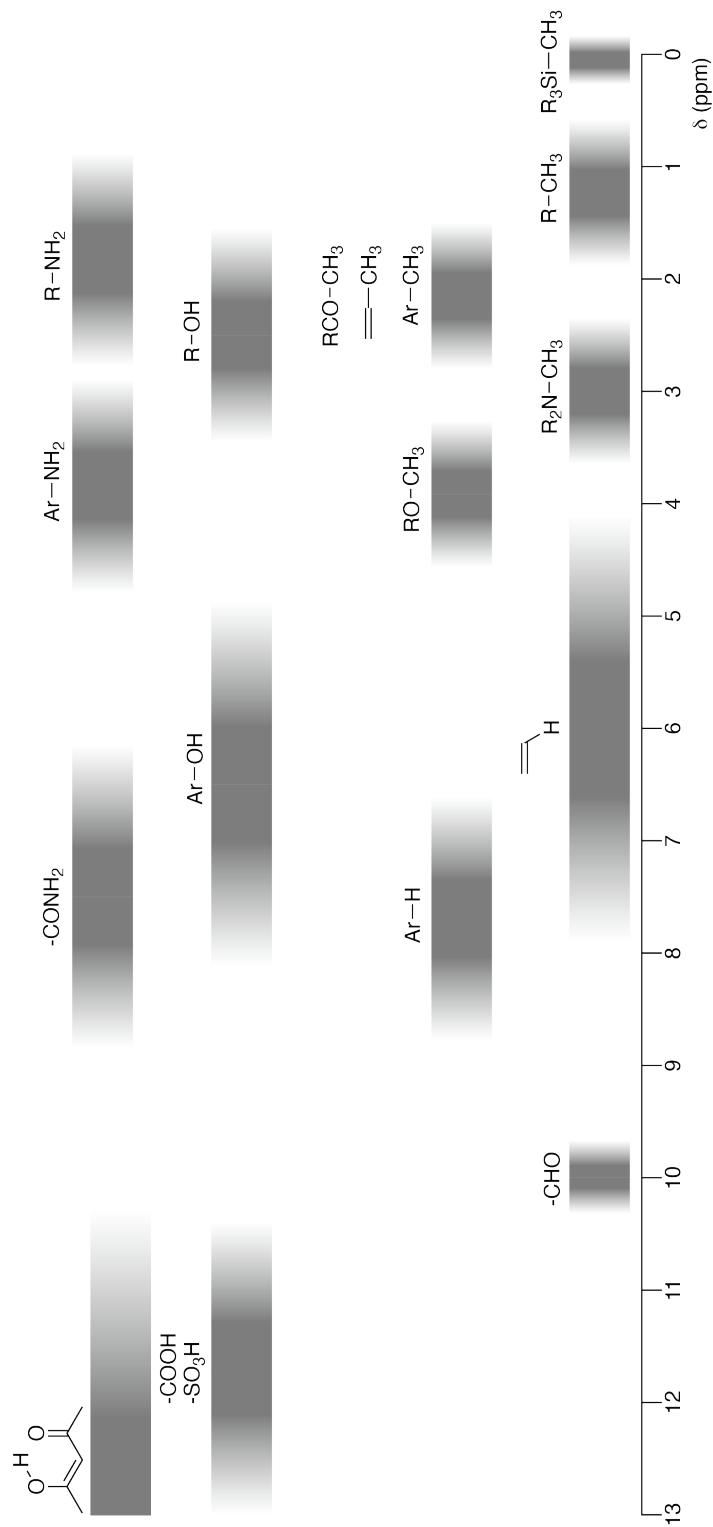

Heat change $\Delta q$	$\Delta q = nc_m\Delta T$ , where $c_m$ is the temperature-independent molar heat capacity.
Nernst equation for redox reaction	$E = E^\circ + \frac{RT}{zF} \ln \frac{C_{\text{ox}}}{C_{\text{red}}}$ , where $C_{\text{ox}}$ is the concentration of oxidized substance, $C_{\text{red}}$ is the concentration of reduced substance.
Arrhenius equation	$k = A \exp\left(-\frac{E_a}{RT}\right)$ , where $k$ is the rate constant, $A$ is the pre-exponential factor, $E_a$ is the activation energy. $\exp(x) = e^x$
Lambert-Beer equation	$A = \varepsilon lc$ , where $A$ is the absorbance, $\varepsilon$ is the molar absorption coefficient, $l$ is the optical path length, $c$ is the concentration of the solution.
Henderson-Hasselbalch equation	For an equilibrium $\text{HA} \rightleftharpoons \text{H}^+ + \text{A}^-$ , where equilibrium constant is $K_a$ , $\text{pH} = \text{p}K_a + \log\left(\frac{[\text{A}^-]}{[\text{HA}]}\right)$
Energy of a photon	$E = h\nu = h\frac{c}{\lambda}$ , where $\nu$ is the frequency, $\lambda$ is the wavelength of the light.
The sum of a geometric series	When $x \neq 1$ , $1 + x + x^2 + \dots + x^n = \sum_{i=0}^n x^i = \frac{1 - x^{n+1}}{1 - x}$
Approximation equation that can be used to solve problems	When $x \ll 1$ , $\frac{1}{1 - x} \simeq 1 + x$

## Hydrogen at a Metal Surface

11 % of the total							
Question	A.1	A.2	B.1	B.2	B.3	B.4	<b>Total</b>
Points	6	4	5	3	3	3	<b>24</b>
Score							

Hydrogen is expected to be a future energy source that does not depend on fossil fuels. Here, we will consider the hydrogen-storage process in a metal, which is related to hydrogen-transport and -storage technology.

### Part A

As hydrogen is absorbed into the bulk of a metal via its surface, let us first consider the adsorption process of hydrogen at the metal surface,  $H_2(g) \rightarrow 2H(ad)$ , where the gaseous and adsorbed states of hydrogen are represented as (g) and (ad), respectively. Hydrogen molecules ( $H_2$ ) that reach the metal surface (M) dissociate at the surface and are adsorbed as H atoms (Fig. 1). Here, the potential energy of  $H_2$  is represented by two variables: the interatomic distance,  $d$ , and the height relative to the surface metal atom,  $z$ . It is assumed that the axis along the two H atoms is parallel to the surface and that the center of gravity is always on the vertical dotted line in Fig. 1. Fig. 2 shows the potential energy contour plot for the dissociation at the surface. The numerical values represent the potential energy in units of kJ per mole of  $H_2$ . The solid line spacing is  $20\text{ kJ mol}^{-1}$ , the dashed line spacing is  $100\text{ kJ mol}^{-1}$ , and the spacing between solid and dashed lines is  $80\text{ kJ mol}^{-1}$ . The zero-point vibration energy is ignored.

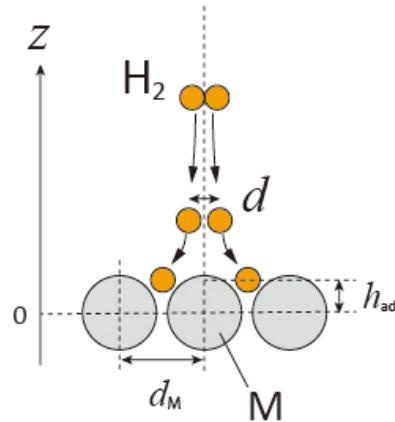

Fig.1 Definition of variables. Drawing is not in scale.

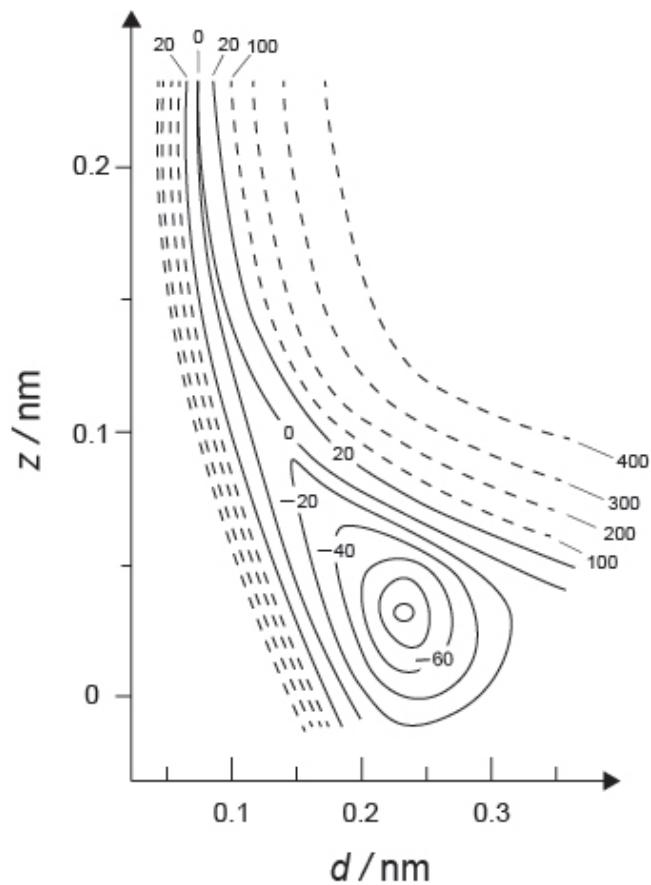

Fig.2

**A.1** For each of the following items (i)–(iii), **select** the closest value from A–G. 6pt

- (i) The interatomic distance for a gaseous H<sub>2</sub> molecule  
(ii) The interatomic distance between metal atoms ( $d_M$  in Fig. 1)  
(iii) The distance of adsorbed H atoms from the surface ( $h_{ad}$  in Fig. 1)

A. 0.03 nm   B. 0.07 nm   C. 0.11 nm   D. 0.15 nm  
E. 0.19 nm   F. 0.23 nm   G. 0.27 nm

**A.2** For each of the following items (i)–(ii), **select** the closest value from A–H. 4pt

- (i) the energy required for the dissociation of gaseous H<sub>2</sub> to gaseous H [H<sub>2</sub>(g) → 2H(g)]  
(ii) the energy released during the adsorption of a gaseous H<sub>2</sub> [H<sub>2</sub>(g) → 2H(ad)]

A. 20 kJ mol<sup>-1</sup>   B. 40 kJ mol<sup>-1</sup>   C. 60 kJ mol<sup>-1</sup>   D. 100 kJ mol<sup>-1</sup>  
E. 150 kJ mol<sup>-1</sup>   F. 200 kJ mol<sup>-1</sup>   G. 300 kJ mol<sup>-1</sup>   H. 400 kJ mol<sup>-1</sup>

## Part B

The adsorbed hydrogen atoms are then either absorbed into the bulk, or recombine and desorb back into the gas phase, as shown in the reactions (1a) and (1b). H(ab) represents a hydrogen atom absorbed in the bulk.

The reaction rates per surface site for adsorption, desorption, and absorption are  $r_1[\text{s}^{-1}]$ ,  $r_2[\text{s}^{-1}]$  and  $r_3[\text{s}^{-1}]$ , respectively. They are expressed as:

$$r_1 = k_1 P_{\text{H}_2} (1 - \theta)^2 \quad (2)$$

$$r_2 = k_2 \theta^2 \quad (3)$$

$$r_3 = k_3 \theta \quad (4)$$

where  $k_1 [\text{s}^{-1} \text{Pa}^{-1}]$ ,  $k_2 [\text{s}^{-1}]$  and  $k_3 [\text{s}^{-1}]$  are the reaction rate constants and  $P_{\text{H}_2}$  is the pressure of  $\text{H}_2$ . Among the sites available on the surface,  $\theta$  ( $0 \leq \theta \leq 1$ ) is the fraction occupied by H atoms. It is assumed that adsorption and desorption are fast compared to absorption ( $r_1, r_2 \gg r_3$ ) and that  $\theta$  remains constant.

**B.1**  $r_3$  can be expressed as:

5pt

$$r_3 = \frac{k_3}{1 + \sqrt{\frac{1}{P_{\text{H}_2} C}}} \quad (5)$$

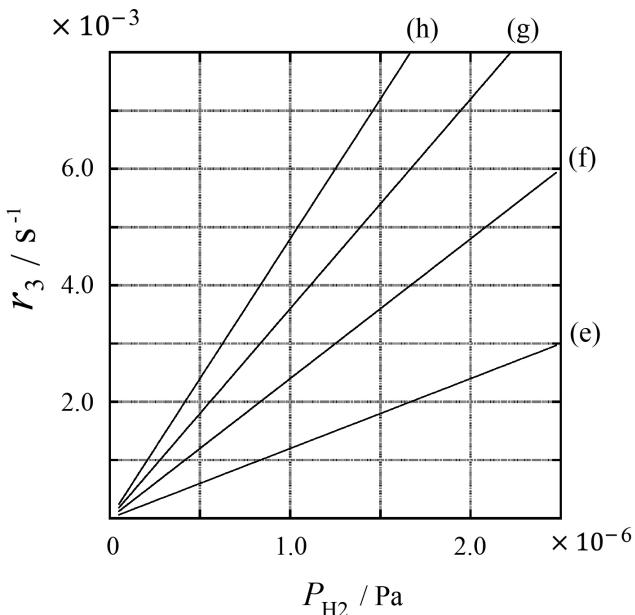

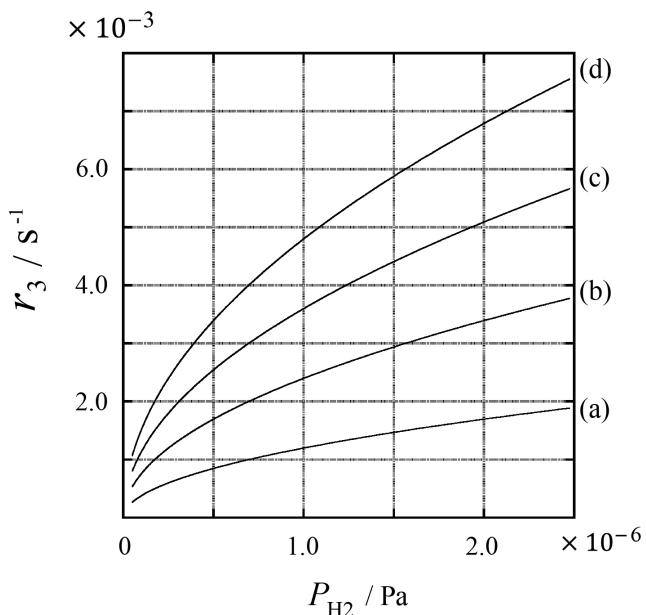

Express  $C$  using  $k_1$  and  $k_2$ .

A metal sample with a surface area of  $S = 1.0 \times 10^{-3} \text{ m}^2$  was placed in a container ( $1\text{L} = 1.0 \times 10^{-3} \text{ m}^3$ ) with  $\text{H}_2$  ( $P_{\text{H}_2} = 1.0 \times 10^2 \text{ Pa}$ ). The density of hydrogen-atom adsorption sites on the surface was  $N = 1.3 \times 10^{18} \text{ m}^{-2}$ . The surface temperature was kept at  $T = 400 \text{ K}$ . As the reaction (1) proceeded,  $P_{\text{H}_2}$  decreased at a constant rate of  $v = 4.0 \times 10^{-4} \text{ Pa s}^{-1}$ . Assume that  $\text{H}_2$  is an ideal gas and that the volume of the metal sample is negligible.

**B.2** Calculate the amount of H atoms in moles absorbed per unit area of the surface per unit time,  $A [\text{mol s}^{-1} \text{ m}^{-2}]$ . 3pt

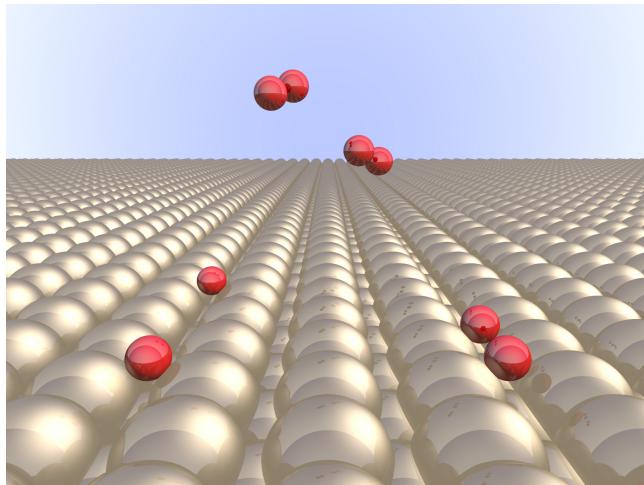

**B.3** At  $T = 400 \text{ K}$ ,  $C$  equals  $1.0 \times 10^2 \text{ Pa}^{-1}$ . Calculate the value of  $k_3$  at  $400 \text{ K}$ . If you did not obtain the answer to **B.2**, use  $A = 3.6 \times 10^{-7} \text{ mol s}^{-1} \text{ m}^{-2}$ . 3pt

**B.4** At a different  $T$ ,  $C = 2.5 \times 10^3 \text{ Pa}^{-1}$  and  $k_3 = 4.8 \times 10^{-2} \text{ s}^{-1}$  are given. For  $r_3$  as a function of  $P_{\text{H}_2}$  at this temperature, select the correct plot from (a)-(h). 3pt

## Vetni á yfirborði málms

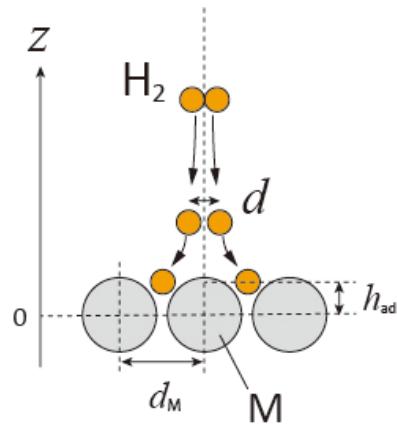

11 % of the total							
Question	A.1	A.2	B.1	B.2	B.3	B.4	<b>Total</b>
Points	6	4	5	3	3	3	<b>24</b>
Score							

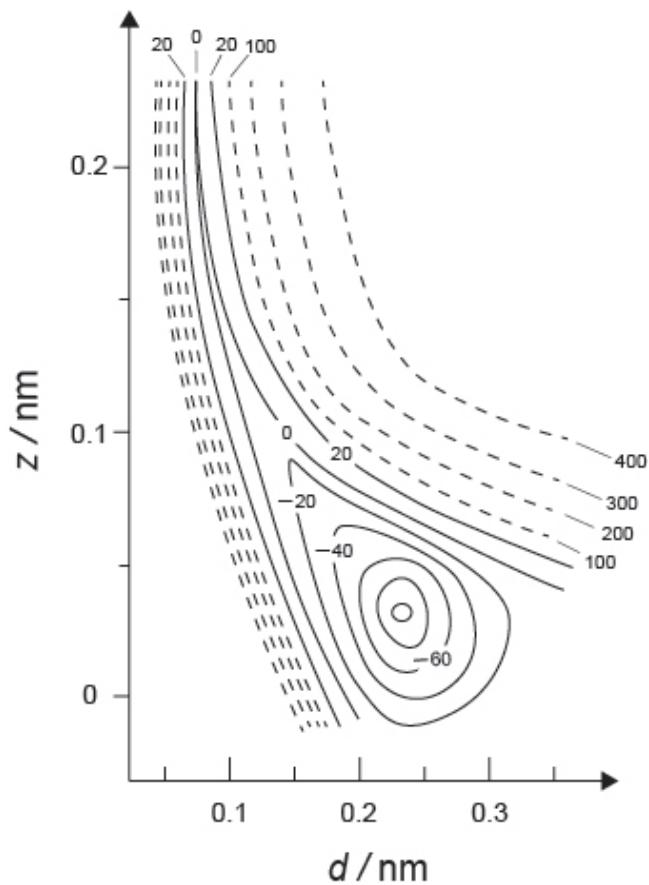

Talið er að vetni verði sá orkugjafi framtíðarinnar sem ekki er háður jarðefnaeldsneyti. Í þessu dæmi er fjallað um geymsluferli vetrnis í málmi en það er skyld flutnings- og geymslutækni fyrir vetrni.

### Hluti A

Þegar vetrni ísogast (absorbs) inn í málum gegnum yfirborð hans, þá þarf fyrst að huga að ásogsferli (adsorption process) vetrnis á málmyfirborðið,  $H_2(g) \rightarrow 2H(ad)$ , þar sem gasástand er táknað með (g) og ásogað ástand með (ad). Vetrnissameindir ( $H_2$ ) sem koma að málmyfirborði (M) klofna þar og ásogast sem H atóm (mynd 1). Mættisorka (potential energy)  $H_2$  er sýnd sem fall af tveimur breytistærðum: fjarlægðinni á milli atómanna,  $d$ , og hæð þeirra frá málmatómi á yfirborði,  $z$ . Gert er ráð fyrir að ásinn milli H atómanna tveggja sé samsíða yfirborðinu og að massamiðja þeirra sé ávallt á lóðréttu punktalínunni á mynd 1. Mynd 2 sýnir hæðarlínur mættisorkunnar fyrir klofnunina á yfirborðinu. Tölgildin sýna mættisorkuna í einingunni  $\text{kJ}$  per mól af  $H_2$ . Bil milli heillína er  $20 \text{ kJ mol}^{-1}$ , bil milli punktastrikaðra lína er  $100 \text{ kJ mol}^{-1}$  og bil milli heillína og punktastrikaðra lína er  $80 \text{ kJ mol}^{-1}$ . Ekki þarf að taka tillit til núllstigsorku titrings (zero-point vibration energy).

Mynd 1 Skilgreiningar á breytistærðum. Teikningin er ekki í réttum hlutföllum.

Mynd 2

**A.1** **Veldu** það gildi af A-G sem kemst næst eftirfarandi stærðum (i)–(iii). 6pt

- (i) Fjarlægðin milli atóma í  $H_2$  gassameind  
(ii) Fjarlægðin milli málmatóma ( $d_M$  á mynd 1)  
(iii) Fjarlægð ásogaðs H atóms frá yfirborðinu ( $h_{ad}$  á mynd 1)

A. 0,03 nm    B. 0,07 nm    C. 0,11 nm    D. 0,15 nm  
E. 0,19 nm    F. 0,23 nm    G. 0,27 nm

**A.2** **Veldu** það gildi A-H sem kemst næst eftirfarandi stærðum (i)–(ii). 4pt

- (i) orkan sem þarf fyrir klofnun  $H_2$  í gasfasa í H atóm í gasfasa  
 $[H_2(g) \rightarrow 2H(g)]$   
(ii) orkan sem losnar við ásog  $H_2$  gass  
 $[H_2(g) \rightarrow 2H(ad)]$

A.  $20 \text{ kJ mol}^{-1}$     B.  $40 \text{ kJ mol}^{-1}$     C.  $60 \text{ kJ mol}^{-1}$     D.  $100 \text{ kJ mol}^{-1}$   
E.  $150 \text{ kJ mol}^{-1}$     F.  $200 \text{ kJ mol}^{-1}$     G.  $300 \text{ kJ mol}^{-1}$     H.  $400 \text{ kJ mol}^{-1}$

**Hluti B**

Ásoguð vetnisatóm geta annaðhvort ísogast inn í málminn eða þau tengjast saman aftur og frásogast (desorb) til baka í gasfasa, eins og sýnt er í efnahörfum (1a) og (1b). H(ab) táknað vetnisatóm sem hefur ísogast inn í málminn.

Hvarfhraðar á hvern ásogsstað yfirborðsins fyrir ásog, frásog og ísog (í sömu röð) eru  $r_1[\text{s}^{-1}]$ ,  $r_2[\text{s}^{-1}]$  og  $r_3[\text{s}^{-1}]$ . Jöfnurnar fyrir hvarfhraðana eru:

$$r_1 = k_1 P_{\text{H}_2} (1 - \theta)^2 \quad (2)$$

$$r_2 = k_2 \theta^2 \quad (3)$$

$$r_3 = k_3 \theta \quad (4)$$

þar sem  $k_1 [\text{s}^{-1} \text{Pa}^{-1}]$ ,  $k_2 [\text{s}^{-1}]$  og  $k_3 [\text{s}^{-1}]$  eru hraðafastarnir og  $P_{\text{H}_2}$  er þrýstingur  $\text{H}_2$ .

Fyrir ásogsstaðina á yfirborðinu þá er  $\theta$  ( $0 \leq \theta \leq 1$ ) sá hluti þeirra sem er setinn  $\text{H}$  atómum. Gert er ráð fyrir að ásog og frásog gerist hratt miðað við ísog ( $r_1, r_2 \gg r_3$ ) og að  $\theta$  sé fasti.

**B.1**  $r_3$  er hægt að lýsa með jöfnunni:

5pt

$$r_3 = \frac{k_3}{1 + \sqrt{\frac{1}{P_{\text{H}_2} C}}} \quad (5)$$

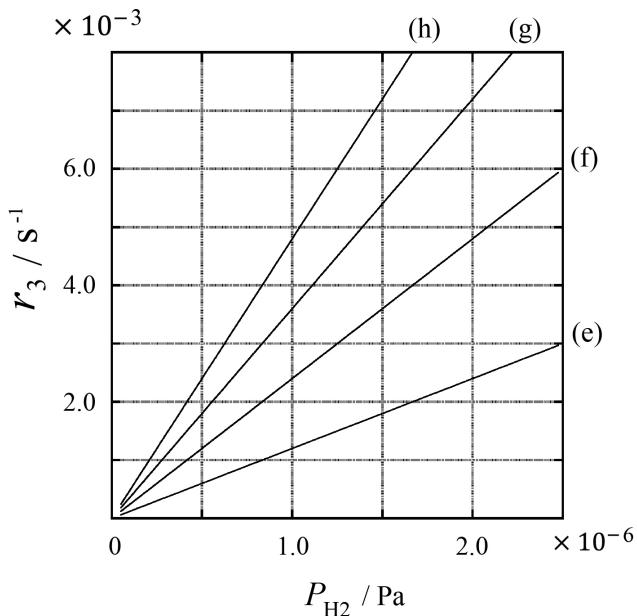

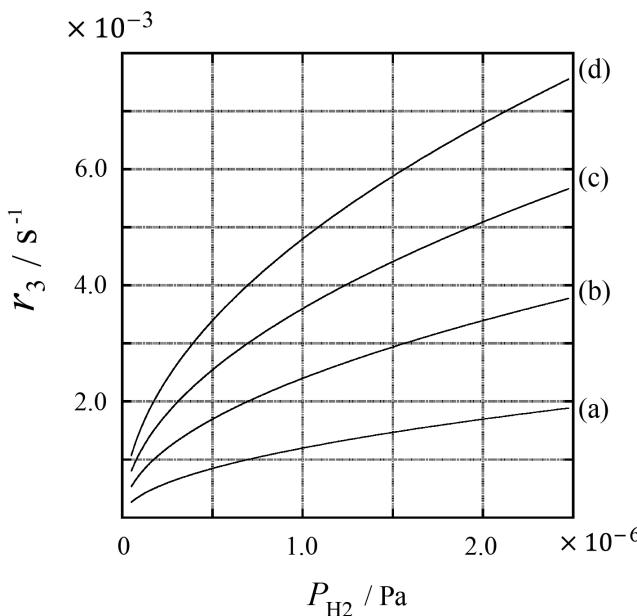

Sýndu jöfnu fyrir  $C$  sem fall  $k_1$  og  $k_2$ .

Málmsýni með yfirborðsflatarmál  $S = 1,0 \times 10^{-3} \text{ m}^2$  var sett í hylki ( $1\text{L} = 1,0 \times 10^{-3} \text{ m}^3$ ) sem innihélt  $\text{H}_2$  ( $P_{\text{H}_2} = 1,0 \times 10^2 \text{ Pa}$ ). Þéttleiki ásogsstaða vetrnisatóma á yfirborðinu var  $N = 1,3 \times 10^{18} \text{ m}^{-2}$ . Hitastiginn á yfirborðinu var haldið við  $T = 400 \text{ K}$ . Eftir því sem hvarfi (1) miðaði áfram lækkaði  $P_{\text{H}_2}$  með jöfnum hraða,  $v = 4,0 \times 10^{-4} \text{ Pa s}^{-1}$ . Gera má ráð fyrir að  $\text{H}_2$  sé kjörgas og að rúmmál málmsýnisins sé óverulegt.

**B.2** **Reiknaðu** mólfjölda ásogaðra H atóma á flatarmálseiningu á tímaeiningu, 3pt  
 $A [\text{mol s}^{-1} \text{ m}^{-2}]$ .

**B.3** Við  $T = 400 \text{ K}$ , er gildi  $C = 1,0 \times 10^2 \text{ Pa}^{-1}$ . **Reiknaðu** gildi  $k_3$  við 400 K. Ef þú gast ekki reiknað svarið í **B.2**, notaðu þá gildið  $A = 3,6 \times 10^{-7} \text{ mol s}^{-1} \text{ m}^{-2}$ . 3pt

**B.4** Við annað hitastig  $T$ , eru gildi  $C = 2,5 \times 10^3 \text{ Pa}^{-1}$  og  $k_3 = 4,8 \times 10^{-2} \text{ s}^{-1}$ . **Veldu** 3pt þann feril af (a)–(h) sem sýnir  $r_3$  sem fall af  $P_{\text{H}_2}$  við þetta hitastig.

## Isotope Time Capsule

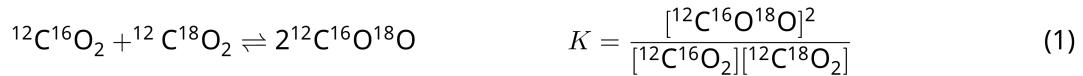

11 % of the total					
Question	A.1	A.2	A.3	A.4	Total
Points	8	8	10	9	<b>35</b>
Score					

Molecular entities that differ only in isotopic composition, such as  $\text{CH}_4$  and  $\text{CH}_3\text{D}$ , are called isotopologues. Isotopologues are considered to have the same chemical characteristics. In nature, however, there exists a slight difference.

Assume that all of the substances shown in this Question are in a gas phase.

Let us consider the following equilibrium:

The entropy,  $S$ , increases with increasing the number of possible microscopic states of a system,  $W$ :

$$S = k_{\text{B}} \ln W \quad (2)$$

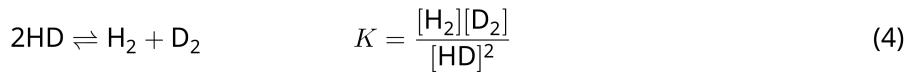

$W = 1$  for  $\text{^{12}C}^{16}\text{O}_2$  and  $\text{^{12}C}^{18}\text{O}_2$ . In contrast,  $W = 2$  for a  $\text{^{12}C}^{16}\text{O}^{18}\text{O}$  molecule because the oxygen atoms are distinguishable in this molecule. As the right-hand side of the equilibrium shown in eq. 1 has two  $\text{^{12}C}^{16}\text{O}^{18}\text{O}$  molecules,  $W = 2^2 = 4$ .

**A.1** The enthalpy change,  $\Delta H$ , of eq. 3 is positive regardless of the temperature. 8pt

**Calculate** the equilibrium constants,  $K$ , for eq. 3 at very low (think of  $T \rightarrow 0$ ) and very high (think of  $T \rightarrow +\infty$ ) temperatures. Assume that the reaction remains unchanged at these temperatures and that  $\Delta H$  converges to a constant value for high temperatures.

The  $\Delta H$  of the following process can be explained by molecular vibrations.

At  $T = 0$  K, the vibrational energy of a diatomic molecule whose vibration frequency is  $\nu$  [ $\text{s}^{-1}$ ] is expressed as:

$$E = \frac{1}{2}h\nu \quad (5)$$

$$\nu = \frac{1}{2\pi} \sqrt{\frac{k}{\mu}} \quad (6)$$

Wherein  $k$  is the force constant and  $\mu$  the reduced mass, which is expressed in terms of the mass of the two atoms in the diatomic molecule,  $m_1$  and  $m_2$ , according to:

$$\mu = \frac{m_1 m_2}{m_1 + m_2} \quad (7)$$

**A.2** The vibration of  $\text{H}_2$  is at  $4161.0 \text{ cm}^{-1}$  when reported as a wavenumber. 8pt  
**Calculate** the  $\Delta H$  of the following equation at  $T = 0$  K in units of  $\text{J mol}^{-1}$ .

Assume that:

- only the vibrational energy contributes to the  $\Delta H$ .
- the  $k$  values for  $\text{H}_2$ ,  $\text{HD}$ , and  $\text{D}_2$  are identical.
- the mass of H to be 1 Da and the mass of D to be 2 Da.

The molar ratio of H<sub>2</sub>, HD, and D<sub>2</sub> depends on the temperature in a system in equilibrium. Here,  $\Delta_{D_2}$  is defined as the change of the molar ratio of D<sub>2</sub>.

$$\Delta_{D_2} = \frac{R_{D_2}}{R_{D_2}^*} - 1 \quad (9)$$

Here,  $R_{D_2}$  refers to  $\frac{[D_2]}{[H_2]}$  in the sample and  $R_{D_2}^*$  to  $\frac{[D_2]}{[H_2]}$  at  $T \rightarrow +\infty$ . It should be noted here that the distribution of isotopes becomes random at  $T \rightarrow +\infty$ .

**A.3** **Calculate**  $\Delta_{D_2}$  with natural D abundance when the isotopic exchange is in equilibrium at the temperature where  $K$  in eq. 4 is 0.300. Assume that the natural abundance ratios of D and H are  $1.5576 \times 10^{-4}$  and  $1 - 1.5576 \times 10^{-4}$ , respectively. 10pt

In general, the molar ratio of the doubly substituted isotopologue, which contains two heavy isotope atoms in one molecule, increases with decreasing temperature. Let us consider the molar ratio of  $\text{CO}_2$  molecules with molecular weights of 44 and 47, which are described as  $\text{CO}_2[44]$  and  $\text{CO}_2[47]$  below. The quantity  $\Delta_{47}$  is defined as:

$$\Delta_{47} = \frac{R_{47}}{R_{47}^*} - 1 \quad (10)$$

$R_{47}$  refers to  $\frac{[\text{CO}_2[47]]}{[\text{CO}_2[44]]}$  in the sample and  $R_{47}^*$  to  $\frac{[\text{CO}_2[47]]}{[\text{CO}_2[44]]}$  at  $T \rightarrow +\infty$ . The natural abundances of carbon and oxygen atoms are shown below; ignore isotopes that are not shown here.

	$^{12}\text{C}$	$^{13}\text{C}$
natural abundance	0.988888	0.011112

	$^{16}\text{O}$	$^{17}\text{O}$	$^{18}\text{O}$
natural abundance	0.997621	0.0003790	0.0020000

The temperature dependence of  $\Delta_{47}$  is determined as follows, where  $T$  is given as the absolute temperature in units of K:

$$\Delta_{47} = \frac{36.2}{T^2} + 2.920 \times 10^{-4} \quad (11)$$

- A.4** The  $R_{47}$  of fossil plankton obtained from the Antarctic seabed was  $4.50865 \times 10^{-5}$ . 9pt  
**Estimate** the temperature using this  $R_{47}$ . This temperature is interpreted as the air temperature during the era in which the plankton lived. Consider only the most common isotopologue of  $\text{CO}_2[47]$  for the calculation.

## Samsætutímaglas

11 % of the total					
Question	A.1	A.2	A.3	A.4	Total
Points	8	8	10	9	<b>35</b>
Score					

Sameindir sem eru ólíkar að því eina leyti að hafa mismunandi samsetningar samsæta, eins og CH<sub>4</sub> og CH<sub>3</sub>D, eru kallaðar samsætuverfur (isotopologues). Samsætuverfur teljast hafa sömu efnaeiginleika en í raun er á þeim smá munur.

Gerðu ráð fyrir að öll efnin í þessu dæmi séu í gasfasa.

Athugum eftirfarandi efnajafnvægi:

$$^{12}\text{C}^{16}\text{O}_2 + ^{12}\text{C}^{18}\text{O}_2 \rightleftharpoons 2^{12}\text{C}^{16}\text{O}^{18}\text{O} \quad K = \frac{[^{12}\text{C}^{16}\text{O}^{18}\text{O}]^2}{[^{12}\text{C}^{16}\text{O}_2][^{12}\text{C}^{18}\text{O}_2]} \quad (1)$$

Óreiðan,  $S$ , eykst með auknum fjölda mögulegra örástanda kerfis,  $W$ :

$$S = k_B \ln W \quad (2)$$

$W = 1$  fyrir  $^{12}\text{C}^{16}\text{O}_2$  og  $^{12}\text{C}^{18}\text{O}_2$ . Hins vegar er  $W = 2$  fyrir  $^{12}\text{C}^{16}\text{O}^{18}\text{O}$  sameind því að hægt er að greina á milli sírefnisatómanna þeirri sameind.

Hægra megin í jafnvæginu (sjá jöfnu 1) eru tvær  $^{12}\text{C}^{16}\text{O}^{18}\text{O}$  sameindir og þar er því  $W = 2^2 = 4$ .

**A.1** Vermibreytingin,  $\Delta H$ , í efnajöfnu 3 er jákvæð við öll hitastig. 8pt

**Reiknaðu** jafnvægisfastann,  $K$ , fyrir efnajafnvægi 3 við mjög lág hitastig (þegar  $T \rightarrow 0$ ) og við mjög há hitastig (þegar  $T \rightarrow +\infty$ ). Gerðu ráð fyrir að hvarfið breytist ekki við þessi hitastig og að  $\Delta H$  nái föstu gildi við há hitastig.

Finna má gildi  $\Delta H$  fyrir eftirfarandi hvarf út frá sameindatitringum.

$$2HD \rightleftharpoons H_2 + D_2 \quad K = \frac{[H_2][D_2]}{[HD]^2} \quad (4)$$

Við  $T = 0$  K, má lýsa titringsorku tvátóma sameindar, sem hefur titringstíðnina  $\nu$  [s<sup>-1</sup>], með eftirfarandi jöfnu:

$$E = \frac{1}{2}h\nu \quad (5)$$

$$\nu = \frac{1}{2\pi} \sqrt{\frac{k}{\mu}} \quad (6)$$

Hér er  $k$  kraftstuðullinn (force constant) og  $\mu$  er skerti massinn (reduced mass), en hann er samsettur úr massa atómanna í tvátóma sameind,  $m_1$  og  $m_2$ , eins og eftirfarandi jafna sýnir:

$$\mu = \frac{m_1 m_2}{m_1 + m_2} \quad (7)$$

**A.2** Titringur  $H_2$  er við 4161,0 cm<sup>-1</sup> (þegar gildið er gefið á formi bylgjutölu (wavenumber)). 8pt

**Reiknaðu**  $\Delta H$  fyrir eftirfarandi efnajöfnu við  $T = 0$  K í eininguunum J mol<sup>-1</sup>.

Gerðu ráð fyrir eftirfarandi:

- $\Delta H$  er aðeins háð titringsorku
- gildi  $k$  fyrir  $H_2$ ,  $HD$ , og  $D_2$  eru þau sömu.
- massi H er 1 Da og massi D er 2 Da.

Í kerfi sem er við jafnvægi eru móhlutföll  $H_2$ ,  $HD$  og  $D_2$  háð hitastigi. Hér er  $\Delta_{D_2}$  skilgreint sem breytingin á móhlutfalli  $D_2$ .

$$\Delta_{D_2} = \frac{R_{D_2}}{R_{D_2}^*} - 1 \quad (9)$$

Hér vísar  $R_{D_2}$  til  $\frac{[D_2]}{[H_2]}$  í sýninu og  $R_{D_2}^*$  til  $\frac{[D_2]}{[H_2]}$  þegar  $T \rightarrow +\infty$ .

Bent skal á að dreifing samsæta er handahófskennnd (random) þegar  $T \rightarrow +\infty$ .

- A.3** **Reiknaðu**  $\Delta_{D_2}$  þegar samsætuskiptin eru í jafnvægi, við það hitastig þegar  $K$  í jöfnu 4 er 0,300.  
Gerðu ráð fyrir að náttúrulegt samsætuhlutfall D sé  $1,5576 \times 10^{-4}$  og náttúrulegt samsætuhlutfall H sé  $1 - 1,5576 \times 10^{-4}$ .

Tvísetin samsætuverfa (doubly substituted isotopologue) inniheldur tvö þung samsætuatóm í einni sameind. Almennt eykst móhlutfall tvísetinna samsætuverfa með lækkandi hitastigi.

Skoðum móhlutfall  $\text{CO}_2$  sameinda sem hafa mólmassana 44 og 47, og sem táknuð eru sem  $\text{CO}_2[44]$  og  $\text{CO}_2[47]$ . Stærðin  $\Delta_{47}$  er skilgreind á eftirfarandi hátt:

$$\Delta_{47} = \frac{R_{47}}{R_{47}^*} - 1 \quad (10)$$

Hér vísar  $R_{47}$  til  $\frac{[\text{CO}_2[47]]}{[\text{CO}_2[44]]}$  í sýninu og  $R_{47}^*$  til  $\frac{[\text{CO}_2[47]]}{[\text{CO}_2[44]]}$  þegar  $T \rightarrow +\infty$ .

Náttúrulegt samsætuhlutfall kolefnis- og súrefnisatóma er sýnt hér að neðan; ekki þarf að taka tillit til annarra samsæta.

	$^{12}\text{C}$	$^{13}\text{C}$
náttúrulegt samsætuhlutfall	0,988888	0,011112

	$^{16}\text{O}$	$^{17}\text{O}$	$^{18}\text{O}$
náttúrulegt samsætuhlutfall	0,997621	0,0003790	0,0020000

Hvernig  $\Delta_{47}$  er háð hitastigi er gefið með jöfnunni hér að neðan, þar sem hitastigið  $T$  er gefið með einingunni K:

$$\Delta_{47} = \frac{36.2}{T^2} + 2.920 \times 10^{-4} \quad (11)$$

**A.4** Gildi  $R_{47}$  í steingervingi svifjurtar frá hafobotni við Suðurskautslandið er 9pt  
 $4,50865 \times 10^{-5}$ .  
 Notaðu þetta gildi á  $R_{47}$  til að **áætla** hitastigið þegar svifjurtin var á lífi. Þetta hitastig er talið vera lofthitinn á þeim tíma þegar svifjurtin var uppi. Í útreikningunum þarf aðeins að nota algengustu samsætuverfu  $\text{CO}_2[47]$ .

## Lambert-Beer Law?

8 % of the total				
Question	A.1	B.1	B.2	Total
Points	10	6	6	<b>22</b>
Score				

In this problem, ignore the absorption of the cell and the solvent. The temperatures of all solutions and gases are kept constant at 25 °C.

### Part A

An aqueous solution **X** was prepared using HA and NaA. The concentrations  $[A^-]$ ,  $[HA]$ , and  $[H^+]$  in solution **X** are  $1.00 \times 10^{-2}$  mol L $^{-1}$ ,  $1.00 \times 10^{-3}$  mol L $^{-1}$ , and  $1.00 \times 10^{-4}$  mol L $^{-1}$ , respectively, which are correlated via the following acid-base equilibrium:

The optical path length is  $l$  in Part A. Ignore the density change upon dilution. Assume that no chemical reactions other than eq 1 occur.

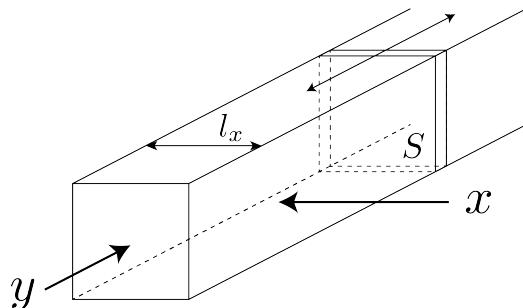

- A.1** The absorbance of **X** was  $A_1$  at a wavelength of  $\lambda_1$ . Then, solution **X** was diluted to twice its initial volume using hydrochloric acid with pH = 2.500. After the dilution, the absorbance was still  $A_1$  at  $\lambda_1$ . **Determine** the ratio  $\varepsilon_{HA}/\varepsilon_{A^-}$ , where  $\varepsilon_{HA}$  and  $\varepsilon_{A^-}$  represent the absorption coefficients of HA and of  $A^-$ , respectively, at  $\lambda_1$ . 10pt

## Part B

Let us consider the following equilibrium in the gas phase.

Pure gas D is filled into a cuboid container that has a transparent movable wall with a cross-section of  $S$  (see the figure below) at a pressure  $P$ , and equilibrium is established while the total pressure is kept at  $P$ . The absorbance of the gas is  $A = \varepsilon(n/V)l$ , where  $\varepsilon$ ,  $n$ ,  $V$ , and  $l$  are the absorption coefficient, amount of the gas in moles, volume of the gas, and optical path length, respectively. Assume that all components of the gas mixture behave as ideal gases.

Use the following definitions if necessary.

	Initial state		After equilibrium	
	D	M	D	M
Partial pressure	$P$	0	$p_D$	$p_M$
Amount in moles	$n_0$	0	$n_D$	$n_M$
Volume		$V_0$		$V$

- B.1** The absorbance of the gas at  $\lambda_{B1}$  measured from direction  $x$  ( $l = l_x$ ) was  $A_{B1}$  both at the initial state and after the equilibrium. **Determine** the ratio  $\varepsilon_D/\varepsilon_M$  at  $\lambda_{B1}$ , where  $\varepsilon_D$  and  $\varepsilon_M$  represent the absorption coefficients of D and of M, respectively. 6pt

- B.2** The absorbance of the gas at  $\lambda_{B2}$  measured from direction  $y$  was  $A_{B2}$  both at the initial state ( $l = l_{y0}$ ) and after the equilibrium ( $l = l_y$ ). **Determine** the ratio  $\varepsilon_D/\varepsilon_M$  at  $\lambda_{B2}$ . 6pt

## Lambert-Beer lögmal?

Score				

Í þessu verkefni skaltu hūnsa gleypni kúvettunnar og leysisins. Hitastigi allra lausna og gastegunda er haldið föstu við 25 °C.

### Hluti A

Vatnslausn **X** var útbúin með HA og NaA. Styrkir  $[A^-]$ ,  $[HA]$ , og  $[H^+]$  í lausninni eru  $1,00 \times 10^{-2}$  mol L $^{-1}$ ,  $1,00 \times 10^{-3}$  mol L $^{-1}$ , og  $1,00 \times 10^{-4}$  mol L $^{-1}$ , (talið upp í sömu röð) og um samband styrkjanna gildir eftirfarandi sýru-basa jafnvægi:

$$HA \rightleftharpoons A^- + H^+ \quad K = \frac{[A^-][H^+]}{[HA]} \quad (1)$$

Lengd geisla í mælilausn (optical path length) er  $l$  í hluta A. Hunsaðu eðlismassabreytingu sem kann að verða við þynningu og gerðu ráð fyrir að jafna 1 sé eina efnahvarfið sem á sér stað.

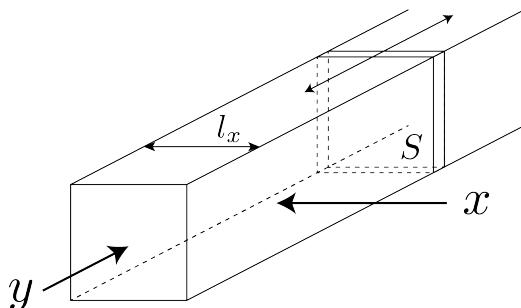

- A.1** Gleypni **X** var  $A_1$  við bylgjulengd  $\lambda_1$ . Síðan var lausn **X** þynnt að tvöföldu upphaflegu rúmmáli lausnarinnar með saltsýru (hydrochloric acid) sem hafði pH = 2,500. Eftir þynningu var gleypnin ennþá  $A_1$  við  $\lambda_1$ . **Ákvarðaðu** hlutfallið  $\varepsilon_{HA}/\varepsilon_{A^-}$ , þar sem  $\varepsilon_{HA}$  og  $\varepsilon_{A^-}$  eru gleypnistuðlar (absorption coefficients) HA og  $A^-$ , við  $\lambda_1$ .

**Hluti B**

Skoðum eftirfarandi efnajafnvægi í gasfasa.

$$D \rightleftharpoons 2M \quad (2)$$

Hreinu gasi D er komið fyrir við þrýsting  $P$  í ferstrendingslagi í láti sem hefur gegnsæja og færarlega hlið með þversnið  $S$  (sjá mynd að neðan). Jafnvægi er komið á meðan heildarþrýstingnum er haldið föstum við  $P$ . Gleypni gassins er  $A = \varepsilon(n/V)l$ , þar sem  $\varepsilon$  er gleypnistuðullinn,  $n$  er mólfjöldi gass,  $V$  er rúmmál gassins og  $l$  er lengd geisla. Gerðu ráð fyrir að allir hlutar gasblöndunnar hegði sér sem kjörgas.

Notaðu eftirfarandi skilgreiningar eftir þörfum:

	Upphafssástand		Við jafnvægi	
	D	M	D	M
Hlutþrýstingur	$P$	0	$p_D$	$p_M$
Mólfjöldi	$n_0$	0	$n_D$	$n_M$
Rúmmál	$V_0$			$V$

**B.1** Gleypni gassins við  $\lambda_{B1}$  þegar mæld eftir stefnu  $x$  ( $l = l_x$ ) var  $A_{B1}$ , bæði við upphafssástand og við jafnvægi. **Ákvarðaðu** hlutfallið  $\varepsilon_D/\varepsilon_M$  við  $\lambda_{B1}$ , þar sem  $\varepsilon_D$  og  $\varepsilon_M$  eru gleypnistuðlar D og M. 6pt

**B.2** Gleypni gassins við  $\lambda_{B2}$  þegar mæld eftir stefnu  $y$  var  $A_{B2}$ , bæði við upphafssástand ( $l = l_{y0}$ ) og við jafnvægi ( $l = l_y$ ). **Ákvarðaðu** hlutfallið  $\varepsilon_D/\varepsilon_M$  við  $\lambda_{B2}$ . 6pt

## The Redox Chemistry of Zinc

11 % of the total						
Question	A.1	A.2	B.1	B.2	B.3	<b>Total</b>
Points	6	5	4	3	5	<b>32</b>
Score						

Zinc has long been used as alloys for brass and steel materials. The zinc contained in industrial wastewater is separated by precipitation to detoxify the water, and the obtained precipitate is reduced to recover and reuse it as metallic zinc.

### Part A

The dissolution equilibrium of zinc hydroxide  $\text{Zn}(\text{OH})_2(s)$  at 25 °C and the relevant equilibrium constants are given in eq. 1–4.

The solubility,  $S$ , of zinc (concentration of zinc in a saturated aqueous solution) is given in eq. 5.

$$S = [\text{Zn}^{2+}(\text{aq})] + [\text{Zn}(\text{OH})_2(\text{aq})] + [\text{Zn}(\text{OH})_4^{2-}(\text{aq})] \quad (5)$$

- A.1** When the equilibria in eq. 1–4 are established, **calculate** the pH range in which  $[\text{Zn}(\text{OH})_2(\text{aq})]$  is the greatest among  $[\text{Zn}^{2+}(\text{aq})]$ ,  $[\text{Zn}(\text{OH})_2(\text{aq})]$  and  $[\text{Zn}(\text{OH})_4^{2-}(\text{aq})]$ . 6pt

- A.2** A saturated aqueous solution of  $\text{Zn}(\text{OH})_2(\text{s})$  with  $\text{pH} = 7.00$  was prepared and filtered.  $\text{NaOH}$  was added to this filtrate to increase its pH to 12.00. **Calculate** the molar percentage of zinc that precipitates when increasing the pH from 7.00 to 12.00. Ignore the volume and temperature changes. 5pt

### Part B

Next, the recovered zinc hydroxide is heated to obtain zinc oxide according to the reaction below:

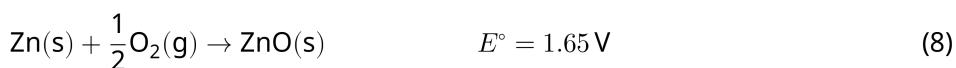

The zinc oxide is then reduced to metallic zinc by reaction with hydrogen:

- B.1** In order for reaction (7) to proceed at a hydrogen pressure kept at 1 bar, it is necessary to reduce the partial pressure of the generated water vapor. **Calculate** the upper limit for the partial pressure of water vapor to allow reaction (7) to proceed at  $300^\circ\text{C}$ . Here, the Gibbs formation energies of zinc oxide and water vapor at  $300^\circ\text{C}$  and 1 bar for all gaseous species are  $\Delta G_{\text{ZnO}}(300^\circ\text{C}) = -2.90 \times 10^2 \text{ kJ mol}^{-1}$  and  $\Delta G_{\text{H}_2\text{O}}(300^\circ\text{C}) = -2.20 \times 10^2 \text{ kJ mol}^{-1}$ , respectively. 4pt

Metallic zinc is used as a negative electrode (anode) material for metal-air batteries. The electrode consists of Zn and  $\text{ZnO}$ . It uses the following redox reaction to generate electricity with the electromotive force (e.m.f.) at  $25^\circ\text{C}$  and pressure of 1 bar,  $E^\circ$ .

- B.2** A zinc-air battery was discharged at 20 mA for 24 hours. **Calculate** the change in mass of the negative electrode (anode) of the battery. 3pt

Mt. Fuji

- B.3** Consider the change of e.m.f. of a zinc-air battery depending on the environment. **Calculate** the e.m.f. at the summit of Mt. Fuji, where the temperature and altitude are  $-38^{\circ}\text{C}$  (February) and 3776 m, respectively. The atmospheric pressure is represented by 5pt

$$P \text{ [bar]} = 1.013 \times \left(1 - \frac{0.0065h}{T + 0.0065h + 273.15}\right)^{5.257} \quad (9)$$

at altitude  $h$  [m] and temperature  $T$  [ $^{\circ}\text{C}$ ]. The molar ratio of oxygen in the atmosphere is 21%. The Gibbs energy change of reaction (8) is  $\Delta G_{\text{ZnO}}(-38^{\circ}\text{C}) = -3.26 \times 10^2 \text{ kJ mol}^{-1}$  at  $-38^{\circ}\text{C}$  and 1 bar.

- B.4** **Calculate** the Gibbs energy change for reaction (6) at  $25^{\circ}\text{C}$ . Note that the standard reduction potentials,  $E^{\circ}(\text{Zn}^{2+}/\text{Zn})$  and  $E^{\circ}(\text{O}_2/\text{H}_2\text{O})$  at  $25^{\circ}\text{C}$  and 1 bar are given as (10) and (11), respectively. 9pt

## Redox efnafræði sinks

11 % of the total							
Question	A.1	A.2	B.1	B.2	B.3	B.4	<b>Total</b>
Points	6	5	4	3	5	9	<b>32</b>
Score							

Sink hefur löngum verið notað í málmlöndur. Sink sem finna má í úrgangsvatni frá iðnaði er aðskilið frá vatninu með fellingu (precipitation), til að afeitra vatnið. Fellingin sem fæst er afoxuð svo að hægt sé að endurheimta sinkið og að lokum endurnýta það sem sinkmálm.

### Hluti A

Leysnijafnvægi sinkhýdroxíðs  $\text{Zn}(\text{OH})_2(s)$  við  $25^\circ\text{C}$  og tilheyrandi jafnvægisfastar er gefið í jöfnum 1-4.

Leysni,  $S$ , sinks (þ.e. styrkur sinks í mettaðri vatnslausn) er gefin með jöfnu 5.

$$S = [\text{Zn}^{2+}(\text{aq})] + [\text{Zn}(\text{OH})_2(\text{aq})] + [\text{Zn}(\text{OH})_4^{2-}(\text{aq})] \quad (5)$$

- A.1** Þegar jafnvægjum 1-4 er náð, **reiknaðu** á hvaða pH bili styrkur  $[\text{Zn}(\text{OH})_2(\text{aq})]$  6pt er hæstur af styrkjum  $[\text{Zn}^{2+}(\text{aq})]$ ,  $[\text{Zn}(\text{OH})_2(\text{aq})]$  og  $[\text{Zn}(\text{OH})_4^{2-}(\text{aq})]$ .

- A.2** Mettuð  $\text{Zn}(\text{OH})_2(\text{s})$  vatnslausn með pH = 7,00 var útbúin og síuð. NaOH var 5pt baett við síuvökvann til að hækka pH hans upp í 12,00.  
**Reiknaðu** mólprósentu sinks sem fellur út þegar pH er hækkað úr 7,00 í 12,00. Hunsaðu rúmmáls- og hitastigsbreytingar.

## Hluti B

Næst var hið endurheimta sinkhýdroxíð hitað og umbreytt í sinkoxíð samkvæmt hvarfinu hér að neðan:

Svo var sinkoxíðið afoxað í sinkmálm, með því að hvarfa það við vetni:

- B.1** Til þess að hvarf (7) geti gengið við fastan 1 bar þrýsting vetrnis, þá er nauðsynlegt að minnka hlutþrýsting vatnsgufunnar sem myndast. **Reiknaðu** efri mörk hlutþrýstings vatnsgufu ef hvarf (7) á að geta gengið við 300 °C. Hér er Gibbs myndunarfríorka sinkoxíðs og vatnsgufu við 300 °C og 1 bar (fyrir öll efni á gasfasa)  $\Delta G_{\text{ZnO}}(300^\circ\text{C}) = -2,90 \times 10^2 \text{ kJ mol}^{-1}$  og  $\Delta G_{\text{H}_2\text{O}}(300^\circ\text{C}) = -2,20 \times 10^2 \text{ kJ mol}^{-1}$ . 4pt

Sinkmálmur er notaður sem efniviður í neikvætt rafskaut (anóðu) í málm-loft rafhlöðum. Rafskautið samanstendur af Zn og ZnO. Það notar eftirfarandi oxunar-afoxunarhvarf til að framkalla rafstraum með íspennu (electromotive force, e.m.f.)  $E^\circ$  við 25 °C og 1 bar.

- B.2** Sink-loft rafhlaða var afhlaðin við 20 mA í 24 klst. **Reiknaðu** massabreytingu 3pt neikvæða rafskautsins (anóðunnar) í rafhlöðunni.

Mt. Fuji

- B.3** Skoðum nú hvernig breyting íspennu í sink-loft rafhlöðu er háð aðstæðum. 5pt  
**Reiknaðu** íspennuna á tindi Mt. Fuji, þar sem hitastig er  $-38^{\circ}\text{C}$  (í febrúar) og hæð fjallsins er 3776 m. Loftþrýstingur er gefinn með

$$P \text{ [bar]} = 1.013 \times \left( 1 - \frac{0.0065h}{T + 0.0065h + 273.15} \right)^{5.257} \quad (9)$$

við hæð  $h$  [m] og hitastig  $T$  [ $^{\circ}\text{C}$ ]. Mólhlfall súrefnis í andrúmslofti er 21%. Gibbs fríorkubreyting hvarfs (8) er  $\Delta G_{\text{ZnO}}(-38^{\circ}\text{C}) = -3,26 \times 10^2 \text{ kJ mol}^{-1}$  við  $-38^{\circ}\text{C}$  og 1 bar.

- B.4** **Reiknaðu** Gibbs fríorkubreytingu hvarfs (6) við  $25^{\circ}\text{C}$ . Staðalafoxunaríspennur,  $E^{\circ}(\text{Zn}^{2+}/\text{Zn})$  og  $E^{\circ}(\text{O}_2/\text{H}_2\text{O})$  við  $25^{\circ}\text{C}$  og 1 bar eru gefnar í jöfnum (10) og (11). 9pt

## Mysterious Silicon

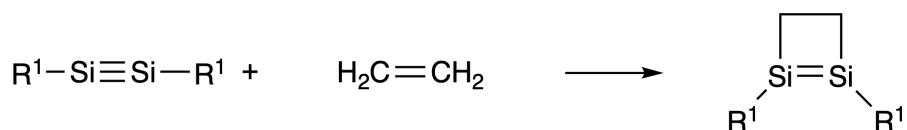

12 % of the total								
Question	A.1	A.2	A.3	A.4	B.1	B.2	B.3	Total
Points	9	7	6	10	5	15	8	<b>60</b>
Score								

Although silicon is also a group 14 element like carbon, their properties differ significantly.

### Part A

Unlike the carbon–carbon triple bond, the silicon–silicon triple bond in a compound formulated as  $R^1\text{—Si}\equiv\text{Si—}R^1$  ( $R$ : organic substituent) is extremely reactive. For example, it reacts with ethylene to form a cyclic product that contains a four-membered ring.

When  $R^1\text{—Si}\equiv\text{Si—}R^1$  is treated with an alkyne ( $R^2\text{—C}\equiv\text{C—}R^2$ ), the four-membered-ring compound **A** is formed as an initial intermediate. Further reaction of another molecule of  $R^2\text{—C}\equiv\text{C—}R^2$  with **A** affords isomers **B** and **C**, both of which have benzene-like cyclic conjugated structures, so-called ‘disilabenzenes’ that contain a six-membered ring and can be formulated as  $(R^1\text{—Si})_2(R^2\text{—C})_4$ .

The  $^{13}C$  NMR analysis of the corresponding six-membered ring skeletons  $Si_2C_4$  shows two signals for **B** and one signal for **C**.

**A.1** **Draw** the structural formulae of **A**, **B**, and **C** using  $R^1$ ,  $R^2$ , Si, and C, with one of the possible resonance structures. 9pt

**A.2** **Calculate** the aromatic stabilization energy (ASE) for benzene and **C** (in the case of  $R^1 = R^2 = H$ ) as positive values, considering the enthalpy change in some hydrogenation reactions of unsaturated systems shown below (Fig. 1). 7pt

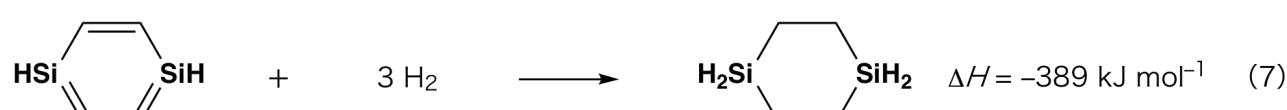

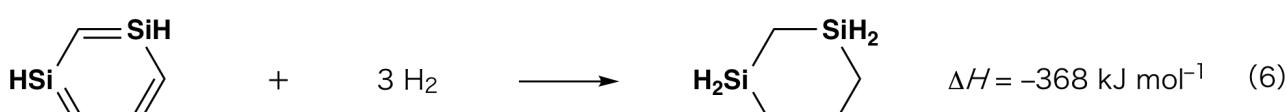

Fig. 1

When a xylene solution of **C** is heated, it undergoes isomerization to give an equilibrium mixture of compounds **D** and **E**. The molar ratio is **D** : **E** = 1 : 40.0 at 50.0 °C and **D** : **E** = 1 : 20.0 at 120.0 °C.

- A.3** **Calculate**  $\Delta H$  for the transformation of **D** to **E**. Assume that  $\Delta H$  does not depend on temperature. 6pt

The isomerization from **C** to **D** and to **E** proceeds via transformations of  $\pi$ -bonds into  $\sigma$ -bonds without breaking any  $\sigma$ -bonds. A  $^{13}\text{C}$  NMR analysis revealed one signal for the  $\text{Si}_2\text{C}_4$  skeleton of **D** and two signals for that of **E**. The skeleton of **D** does not contain any three-membered rings, while **E** has two three-membered rings that share an edge.

- A.4** **Draw** the structural formulae of **D** and **E** using  $\text{R}^1$ ,  $\text{R}^2$ , Si, and C. 10pt

## Part B

Silicon is able to form highly coordinated compounds (> four substituents) with electronegative elements such as fluorine. As metal fluorides are often used as fluorination reagents, highly coordinated silicon fluorides also act as fluorination reagents.

The fluorination reaction of  $\text{CCl}_4$  using  $\text{Na}_2\text{SiF}_6$  was carried out as follows.

- **Standardization of  $\text{Na}_2\text{SiF}_6$  solution :**

• Preparation

Aqueous solution **F**: 0.855 g of  $\text{Na}_2\text{SiF}_6$  ( $188.053 \text{ g mol}^{-1}$ ) dissolved in water (total volume: 200 mL).

Aqueous solution **G**: 6.86 g of  $\text{Ce}_2(\text{SO}_4)_3$  ( $568.424 \text{ g mol}^{-1}$ ) dissolved in water (total volume: 200 mL).

• Procedure

Precipitation titration of a solution **F** (50.0 mL) by dropwise adding solution **G** in the presence of xylenol orange, which coordinates to  $\text{Ce}^{3+}$ , as an indicator. After adding 18.8 mL of solution **G**, the color of the solution changes from yellow to magenta. The generated precipitate is a binary compound that contains  $\text{Ce}^{3+}$ , and the only resulting silicon compound is  $\text{Si}(\text{OH})_4$ .

- B.1** **Write** the balanced equation for the reaction of  $\text{Na}_2\text{SiF}_6$  with  $\text{Ce}_2(\text{SO}_4)_3$ . 5pt

- **Reaction of  $\text{CCl}_4$  with  $\text{Na}_2\text{SiF}_6$ :**

(Substance losses by e.g. evaporation are negligible during the following operations.)

$\text{Na}_2\text{SiF}_6(x \text{ [g]})$  was added to  $\text{CCl}_4$  (500.0 g) and heated to 300 °C in a sealed pressure-resistant reaction vessel. The unreacted  $\text{Na}_2\text{SiF}_6$  and generated  $\text{NaCl}$  were removed by filtration. The filtrate was diluted to a total volume of 1.00 L with  $\text{CCl}_4$  (solution **H**). The  $^{29}\text{Si}$  and  $^{19}\text{F}$  NMR spectra of solution **H** showed  $\text{SiF}_4$  as the only silicon compound. In the  $^{19}\text{F}$  NMR spectrum, in addition to  $\text{SiF}_4$ , signals corresponding to  $\text{CFCl}_3$ ,  $\text{CF}_2\text{Cl}_2$ ,  $\text{CF}_3\text{Cl}$ , and  $\text{CF}_4$  were observed (cf. Table 1). The integration ratios in the  $^{19}\text{F}$  NMR spectrum are proportional to the number of fluorine nuclei.

Table 1

$^{19}\text{F}$ NMR data	$\text{CFCl}_3$	$\text{CF}_2\text{Cl}_2$	$\text{CF}_3\text{Cl}$	$\text{CF}_4$
Integration ratio	45.0	65.0	18.0	2.0

$\text{SiF}_4$  is hydrolyzed to form  $\text{H}_2\text{SiF}_6$  according to the following eq. 8:

Solution **H** (10 mL) was added to an excess amount of water, which resulted in the complete hydrolysis of  $\text{SiF}_4$ . After separation, the  $\text{H}_2\text{SiF}_6$  generated from the hydrolysis in the aqueous solution was neutralized and completely converted to  $\text{Na}_2\text{SiF}_6$  (aqueous solution **J**).

The precipitate of unreacted  $\text{Na}_2\text{SiF}_6$  and  $\text{NaCl}$ , which was removed by filtration in the initial step (underlined), was completely dissolved in water to give an aqueous solution (solution **K**; 10.0 L).

Then, additional precipitation titrations using solution **G** were carried out, and the endpoints of the titrations with **G** were as follows:

- For solution **J** (entire amount): 61.6 mL.
- For 100 mL of solution **K**: 44.4 mL.

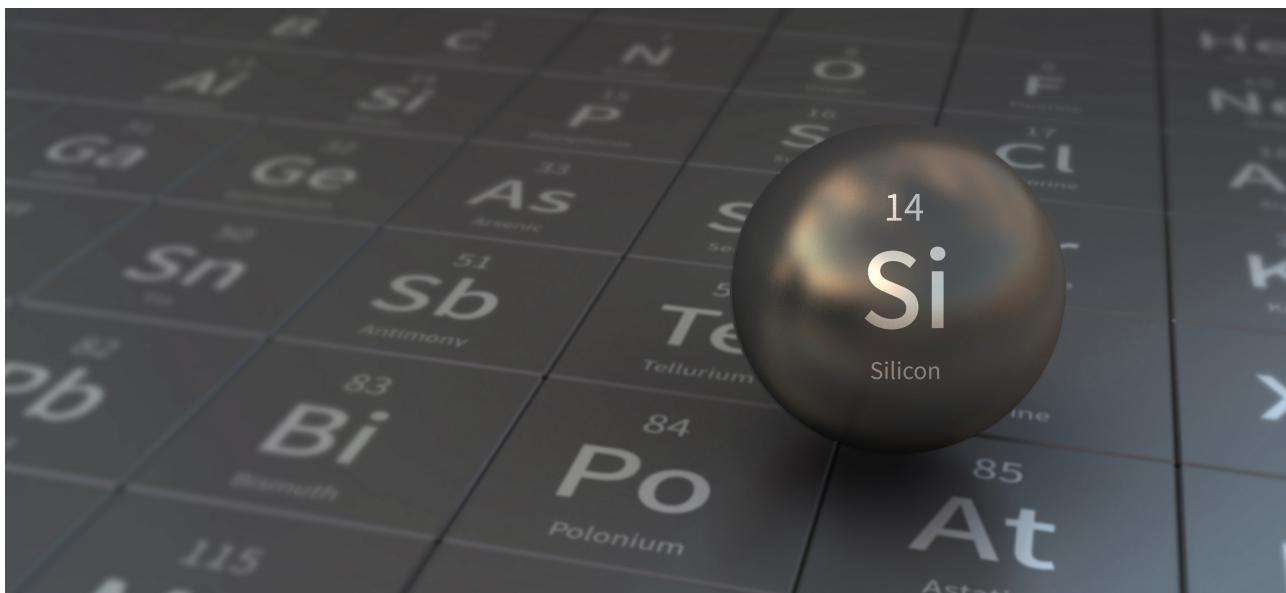

It should be noted here that the coexistence of  $\text{NaCl}$  or  $\text{SiO}_2$  has no effect on the precipitation titration.

**B.2** **Calculate** the mass of the  $\text{NaCl}$  produced in the reaction vessel (information **15pt** underlined), and **calculate** the mass ( $x$  [g]) of the  $\text{Na}_2\text{SiF}_6$  used as a starting material.

**B.3** 77.8% of the  $\text{CCl}_4$  used as a starting material was unreacted. **Calculate** the mass **8pt** of  $\text{CF}_3\text{Cl}$  generated.

## Hinn dularfulli kísill

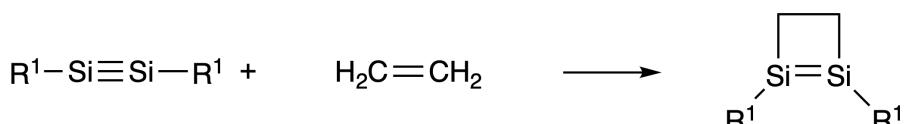

12 % of the total								
Question	A.1	A.2	A.3	A.4	B.1	B.2	B.3	Total
Points	9	7	6	10	5	15	8	<b>60</b>
Score								

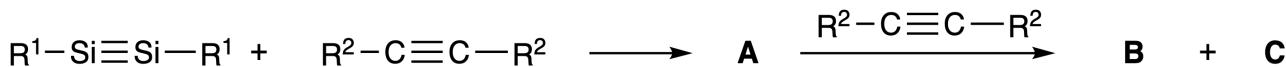

Þótt kísill sé frumefni í flokki 14, eins og kolefni, þá er verulegur munur á eiginleikum þessara efna.

### Hluti A

Ólíkt kolefnis-kolefnis þrítengi, þá er kísil-kísil þrítengi í efnasambandi (táknað með  $R^1-Si \equiv Si-R^1$  ( $R$ : lífrænn sethópur)), gríðarlega hvarfgjarnt. Til dæmis hvarfast það við etýlen svo það myndast hringlaga myndefni sem inniheldur fjórhring.

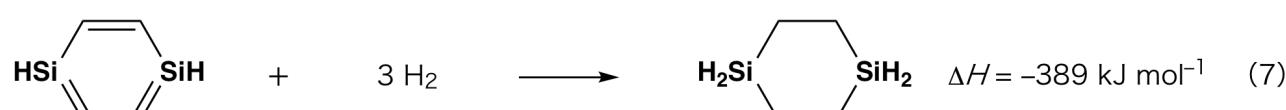

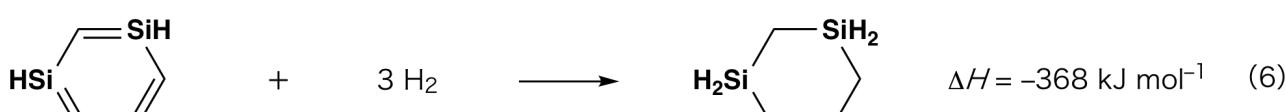

Þegar  $R^1-Si \equiv Si-R^1$  er meðhöndlað með alkýn ( $R^2-C \equiv C-R^2$ ), myndast fyrst milliefnið **A**, sem er fjórhringur. **A** hvarfast áfram við aðra  $R^2-C \equiv C-R^2$  sameind og það leiðir til myndunar á ísómerum **B** og **C**, en þær hafa báðar bensen-líka (arómatiska) byggingu. **B** og **C** eru svokölluð dísílabensen sem innihalda sexhring og þau má tákna með  $(R^1-Si)_2(R^2-C)_4$ .

$^{13}C$  NMR greining á byggingum sexhringjanna  $Si_2C_4$  sýnir tvö merki (signals) fyrir **B** og eitt merki fyrir **C**.

**A.1** **Teiknaðu** byggingar **A**, **B** og **C**, með því að nota  $R^1$ ,  $R^2$ , Si, og C. Það nægir að teikna eina vokmynd hvers efnis. 9pt

**A.2** **Reiknaðu** arómatískar stöðgunarorku (aromatic stabilization energy (ASE)) fyrir bensen og fyrir **C** (fyrir tilfellið  $R^1 = R^2 = H$ ) sem jákvætt gildi. Notaðu vermbreytingu sumra vetrnarhvarfanna á ómettuðum efnum, sem sýnd eru að neðan á mynd 1. 7pt

Mynd 1

Þegar xýlen (xylene) lausn efnis **C** er hituð, ísómerast efnið og fæst þá jafnvægisblanda af efnasamböndum **D** og **E**. Mólhlfutfallið er **D : E = 1 : 40,0** við  $50,0\text{ }^{\circ}\text{C}$  og **D : E = 1 : 20,0** við  $120,0\text{ }^{\circ}\text{C}$ .

- A.3** **Reiknaðu**  $\Delta H$  fyrir umbreytinguna úr **D** í **E**. Gerðu ráð fyrir að  $\Delta H$  sé ekki háð 6pt hitastigi.

Ísómerunin úr **C** í **D** og **E** verður vegna umbreytinga  $\pi$ -tengja yfir í  $\sigma$ -tengi án þess að nokkur  $\sigma$ -tengi rofni.  $^{13}\text{C}$  NMR greining sýndi eitt merki fyrir  $\text{Si}_2\text{C}_4$  hringinn í **D** og tvö merki í **E**. Byggingargrind hrings **D** inniheldur enga þríhringi, en byggingargrind hrings **E** inniheldur tvo þríhringi sem hafa sameiginlegt tengi.

- A.4** **Teiknaðu** byggingu efna **D** og **E** með því að nota  $\text{R}^1$ ,  $\text{R}^2$ , Si, og C. 10pt

## Hluti B

Í efnasamböndum hefur kísill mikla tengigetu með rafneikvæðum (electronegative) frumefnum eins og flúori (getur tengst fleiri en fjórum atómum). Nú eru málflúoríð gjarnan notuð sem flúorunar-hvarfefni. Kísilflúoríð má einnig nota sem flúorunarefni þegar kísillinn tengist mörgum tengihópum.

$\text{Na}_2\text{SiF}_6$  var notað í flúorunahvarf  $\text{CCl}_4$  sem framkvæmt var á eftirfarandi hátt:

- **Stöðlun  $\text{Na}_2\text{SiF}_6$  lausnar :**

· Undirbúnningar

Vatnslausn **F**: 0,855 g af  $\text{Na}_2\text{SiF}_6$  ( $188,053\text{ g mol}^{-1}$ ) leyst upp í vatni (heildarrúmmál 200 mL).

Vatnslausn **G**: 6,86 g af  $\text{Ce}_2(\text{SO}_4)_3$  ( $568,424\text{ g mol}^{-1}$ ) leyst upp í vatni (heildarrúmmál 200 mL).

· Framkvæmd

Fellitítrun (precipitation titration) á lausn **F** (50,0 mL) með því að bæta lausn **G** út í í dropatali, í viðurvist xylenol orange efnavita, sem bindst  $\text{Ce}^{3+}$ . Eftir viðbót 18,8 mL af lausn **G**, breyttist litur lausnarinnar úr gulum yfir í fjólubleikan. Botnfallið sem myndaðist er tvíefni (binary compound) sem inniheldur  $\text{Ce}^{3+}$ , og eina kísil-efnasambandið sem myndaðist er  $\text{Si(OH)}_4$ .

- B.1** **Skrifaðu** stillta efnajöfnu fyrir hvarf  $\text{Na}_2\text{SiF}_6$  með  $\text{Ce}_2(\text{SO}_4)_3$ . 5pt

- **Hvarf  $\text{CCl}_4$  með  $\text{Na}_2\text{SiF}_6$ :**

(Magn þess efnis sem kann að tapast t.d. vegna uppgufunar er hverfandi í eftirfarandi framkvæmd.)

$\text{Na}_2\text{SiF}_6(x\text{ [g]})$  var bætt út í  $\text{CCl}_4$  (500,0 g) og hitað að  $300\text{ }^{\circ}\text{C}$  í lokuðu þrýstibolnu hvarfhylki. Óhvarfað  $\text{Na}_2\text{SiF}_6$  og  $\text{NaCl}$  sem myndaðist var síði frá. Síuvökvinn var þynntur að heildarrúmmáli 1,00 L með  $\text{CCl}_4$  (lausn **H**).  $^{29}\text{Si}$  og  $^{19}\text{F}$  NMR róf af lausn **H** sýndu að  $\text{SiF}_4$  var eina kísil-efnasambandið. Í  $^{19}\text{F}$  NMR rófinu sást, að auk  $\text{SiF}_4$  voru merki sem svara til  $\text{CFCl}_3$ ,  $\text{CF}_2\text{Cl}_2$ ,  $\text{CF}_3\text{Cl}$ , og  $\text{CF}_4$  (Tafla 1). Heildunarhlutföll (integration ratio) í  $^{19}\text{F}$  NMR rófinu eru í réttu hlutfalli við fjölda flúorkjarna.

Tafla 1

$^{19}\text{F}$ NMR	$\text{CFCl}_3$	$\text{CF}_2\text{Cl}_2$	$\text{CF}_3\text{Cl}$	$\text{CF}_4$
Heildunarhlutfall	45,0	65,0	18,0	2,0

$\text{SiF}_4$  er vatnað svo það myndast  $\text{H}_2\text{SiF}_6$  samkvæmt efnajöfnu 8:

Þegar lausn **H** (10 mL) var bætt út í yfirmagn vatns, vatnaðist  $\text{SiF}_4$  að fullu. Það  $\text{H}_2\text{SiF}_6$  sem myndaðist við hvarfið var aðskilið frá lausninni. Það var hlutleyst og umbreytt að fullu í  $\text{Na}_2\text{SiF}_6$  (vatnslausn **J**).

Botnfallið sem innihélt hið óhvarfaða  $\text{Na}_2\text{SiF}_6$  og  $\text{NaCl}$ , sem var síað frá í upphafsskrefinu (undirstrikað í texta) var leyst upp að fullu í vatni, og fékkst þá vatnslausn **K** (10,0 L)

Næst voru framkvæmdar fellitítranir með lausn **G**. Endapunktar þessara titrana voru eftirfarandi:

- Fyrir lausn **J** (öll lausnin) þurfti 61,6 mL af lausn **G**
- Fyrir 100 mL af lausn **K** þurfti 44,4 mL af lausn **G**

Vert er að taka fram að  $\text{NaCl}$  og  $\text{SiO}_2$  hafa engin áhrif á fellitítrunina.

**B.2** **Reiknaðu** massa  $\text{NaCl}$  sem myndaðist í hvarfhyllinu (undirstrikað í texta), og **reiknaðu** massa ( $x$  [g]) af  $\text{Na}_2\text{SiF}_6$  sem var notað sem upphafsefni. 15pt

**B.3** 77,8% af því  $\text{CCl}_4$  sem var notað sem upphafsefni, var óhvarfað. **Reiknaðu** 8pt massa  $\text{CF}_3\text{Cl}$  sem myndaðist.

Volcano at Sakurajima island

### Part A

Japan is one of the countries with the highest numbers of volcanos worldwide. When silicate minerals crystallize from magma, a part of the transition-metal ions ( $M^{n+}$ ) in the magma is incorporated into the silicate minerals. The  $M^{n+}$  studied in the problem are coordinated by oxide ions ( $O^{2-}$ ) and adopt a four-coordinate tetrahedral ( $T_d$ ) geometry in the magma and six-coordinate octahedral ( $O_h$ ) geometry in the silicate minerals, both of which exhibit a high-spin electron configuration. The distribution coefficient of  $M^{n+}$  between the silicate minerals and magma,  $D$ , can be expressed by:

$$D = \frac{[M]_s}{[M]_l}$$

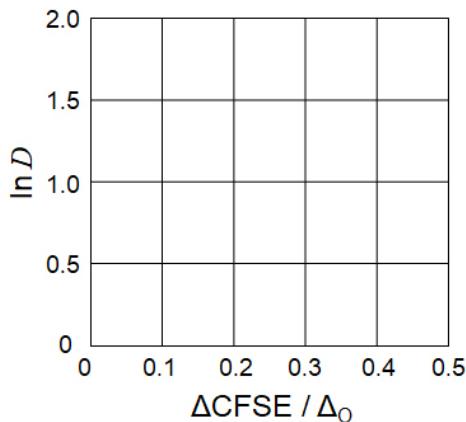

where  $[M]_s$  and  $[M]_l$  are the concentrations of  $M^{n+}$  in the silicate minerals and the magma, respectively. The table below shows the  $D$  values of  $Cr^{2+}$  and  $Mn^{2+}$  as examples.

	$Cr^{2+}$	$Mn^{2+}$
$D$	7.2	1.1

Let  $\Delta_O$  and  $\text{CFSE}^O$  be the energy separation of the d-orbitals of  $M^{n+}$  and the crystal-field stabilization energy in a  $O_h$  field, respectively. Let  $\Delta_T$  and  $\text{CFSE}^T$  be those in a  $T_d$  field.

- A.1** **Calculate**  $|\text{CFSE}^O - \text{CFSE}^T| = \Delta\text{CFSE}$  in terms of  $\Delta_O$  for  $\text{Cr}^{2+}$ ,  $\text{Mn}^{2+}$ , and  $\text{Co}^{2+}$ ; 6pt  
assume  $\Delta_T = 4/9\Delta_O$ .

- A.2** A linear relationship is observed by plotting  $\ln D$  against  $\Delta\text{CFSE} / \Delta_O$  in the Cartesian coordinate system shown below. 3pt  
**Estimate**  $D$  for  $\text{Co}^{2+}$ .

Metal oxides  $\text{MO}$  ( $\text{M}$ : Ca, Ti, V, Mn, or Co) crystallize in a rock-salt structure wherein the  $\text{M}^{n+}$  adopts an  $O_h$  geometry with a high-spin electron configuration. The lattice enthalpy of these oxides is mainly governed by the Coulomb interactions based on the radius and charge of the ions and some contributions from the CFSE of  $\text{M}^{n+}$  in the  $O_h$  field.

- A.3** **Choose** the appropriate set of lattice enthalpies [ $\text{kJ mol}^{-1}$ ] from one of the options (a) to (f). 3pt

	<b>CaO</b>	<b>TiO</b>	<b>VO</b>	<b>MnO</b>	<b>CoO</b>
<b>(a)</b>	3460	3878	3913	3810	3916
<b>(b)</b>	3460	3916	3878	3810	3913
<b>(c)</b>	3460	3913	3916	3810	3878
<b>(d)</b>	3810	3878	3913	3460	3916
<b>(e)</b>	3810	3916	3878	3460	3913
<b>(f)</b>	3810	3913	3916	3460	3878

**Part B**

A mixed oxide **A**, which contains  $\text{La}^{3+}$  and  $\text{Cu}^{2+}$ , crystallizes in a tetragonal unit cell shown in Fig.1. In the  $[\text{CuO}_6]$  octahedron, the Cu-O length along the z-axis ( $l_z$ ) is longer than that of the x-axis ( $l_x$ ), and  $[\text{CuO}_6]$  is distorted from the regular  $O_h$  geometry. This distortion removes the degeneracy of the  $e_g$  orbitals ( $d_{x^2-y^2}$  and  $d_{z^2}$ ).

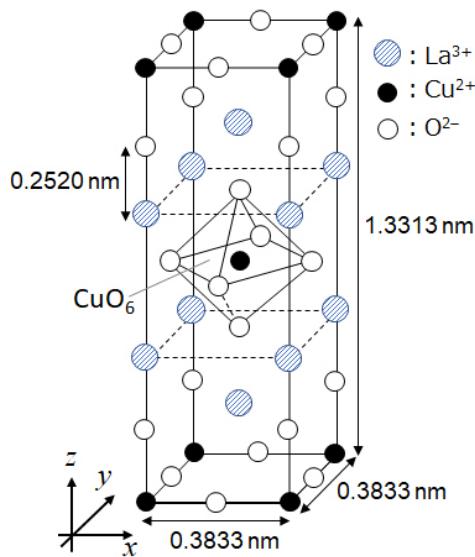

Fig. 1

**A** can be synthesized by thermal decomposition (pyrolysis) of complex **B**, which is formed by mixing metal chlorides in dilute aqueous ammonia solution containing squaric acid  $\text{C}_4\text{H}_2\text{O}_4$ , i.e., a diacid. The pyrolysis behavior of **B** in dry air shows a weight loss of 29.1% up to 200 °C due to the loss of crystallization water, followed by another weight loss up to 700 °C due to the release of  $\text{CO}_2$ . The total weight loss during the formation of **A** from **B** is 63.6%. It should be noted that only water and  $\text{CO}_2$  are released in the pyrolysis reaction.

<b>B.1</b>	<u>Write</u> the chemical formulae for <b>A</b> and <b>B</b> .	6pt
------------	--	-----

<b>B.2</b>	<u>Calculate</u> $l_x$ and $l_z$ using Fig. 1.	4pt
------------	--	-----

<b>B.3</b>	For $\text{Cu}^{2+}$ in the distorted $[\text{CuO}_6]$ octahedron in <b>A</b> of Fig. 1, <u>write</u> the names of the split $e_g$ orbitals ( $d_{x^2-y^2}$ and $d_{z^2}$ ) in (i) and (ii), and <u>draw</u> the electron configuration in the dotted box in your answer sheet.	4pt
------------	---	-----

**A** is an insulator. When one  $\text{La}^{3+}$  is substituted with one  $\text{Sr}^{2+}$ , one hole is generated in the crystal lattice that can conduct electricity. As a result, the  $\text{Sr}^{2+}$ -doped **A** shows superconductivity below 38 K. When a substitution reaction took place for **A**,  $2.05 \times 10^{27}$  holes  $\text{m}^{-3}$  were generated.

- B.4** **Calculate** the percentage of  $\text{Sr}^{2+}$  substituted for  $\text{La}^{3+}$  based on the mole ratio 4pt in the substitution reaction. Note that the valences of the constituent ions and the crystal structure are not altered by the substitution reaction.

### Part C

$\text{Cu}_2(\text{CH}_3\text{CO}_2)_4$  is composed of four  $\text{CH}_3\text{CO}_2^-$  coordinated to two  $\text{Cu}^{2+}$  (Fig. 2A).  $\text{Cu}_2(\text{CH}_3\text{CO}_2)_4$  exhibits high levels of structural symmetry, with two axes passing through the carbon atoms of the four  $\text{CH}_3\text{CO}_2^-$  and an axis passing through the two  $\text{Cu}^{2+}$ , all of which are oriented orthogonal relative to each other. When a dicarboxylate ligand is used instead of  $\text{CH}_3\text{CO}_2^-$ , a "cage complex" is formed. The cage complex  $\text{Cu}_4(\text{L1})_4$  is composed of planar dicarboxylate **L1** (Fig. 2B) and  $\text{Cu}^{2+}$  (Fig. 2C). The angle  $\theta$  between the coordination directions of the two carboxylates, indicated by the arrows in Fig. 2B, determines the structure of the cage complex. The  $\theta$  is  $0^\circ$  for **L1**. Note that hydrogen atoms are not shown in Fig. 2.

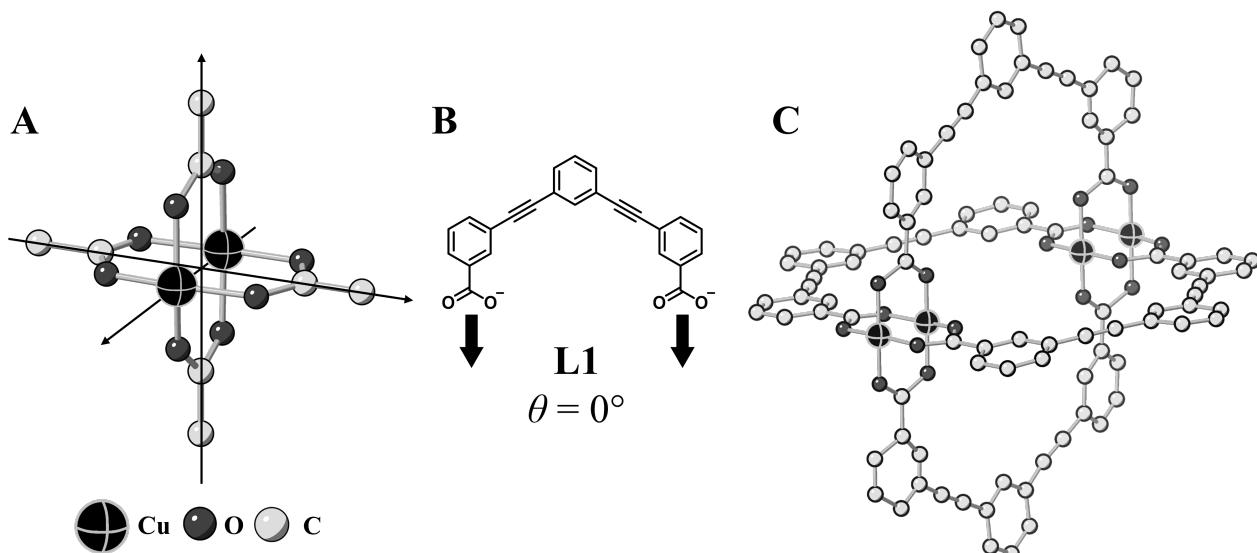

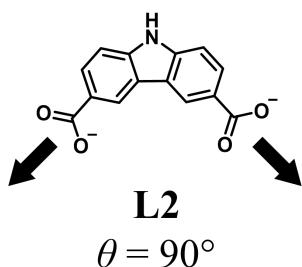

Fig. 2

- C.1** The  $\theta$  of the planar dicarboxylate **L2** below is fixed to  $90^\circ$ . If the composition of the cage complex formed from **L2** and  $\text{Cu}^{2+}$  is  $\text{Cu}_n(\text{L2})_m$ , give the smallest integer combination of  $n$  and  $m$ . Assume that only the  $\text{CO}_2^-$  groups of **L2** form a coordination bond to  $\text{Cu}^{2+}$  ions. 5pt

A zinc complex,  $\text{Zn}_4\text{O}(\text{CH}_3\text{CO}_2)_6$ , contains four tetrahedral  $\text{Zn}^{2+}$ , six  $\text{CH}_3\text{CO}_2^-$ , and one  $\text{O}^{2-}$  (Fig. 3A). In  $\text{Zn}_4\text{O}(\text{CH}_3\text{CO}_2)_6$ , the  $\text{O}^{2-}$  is located at the origin, and the three axes passing through the carbon atoms of  $\text{CH}_3\text{CO}_2^-$  are oriented orthogonal relative to each other. When *p*-benzenedicarboxylate (Fig. 3B, **L3**,  $\theta = 180^\circ$ ) is used instead of  $\text{CH}_3\text{CO}_2^-$ , the  $\text{Zn}^{2+}$  clusters are linked to each other to form a crystalline solid (**X**) that is called a “porous coordination polymer” (Fig. 3C). The composition of **X** is  $[\text{Zn}_4\text{O}(\text{L3})_3]_n$ , and it has a cubic crystal structure with nano-sized pores. One pore is represented as a sphere in Fig. 3D, and each tetrahedral  $\text{Zn}^{2+}$  cluster is represented as a dark gray polyhedron in Fig. 3C and 3D. Note that hydrogen atoms are not shown in Fig. 3.

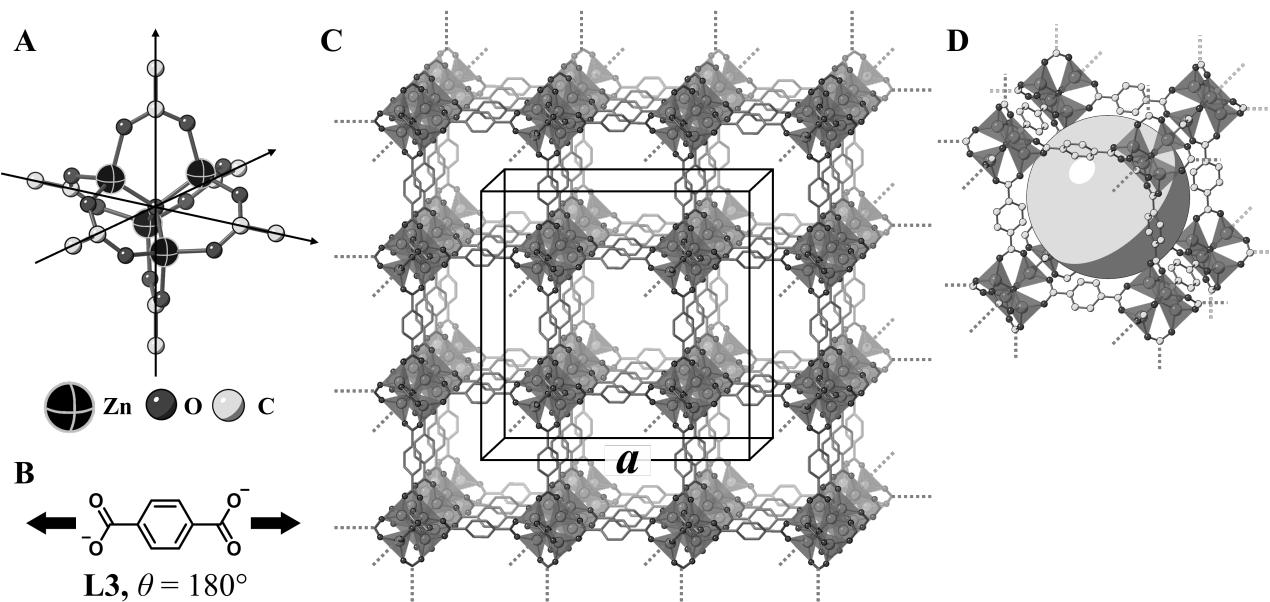

Fig. 3

- C.2** **X** has a cubic unit cell with a side length of  $a$  (Fig. 3C) and a density of  $0.592 \text{ g cm}^{-3}$ . **Calculate**  $a$  in [cm]. 5pt

- C.3** **X** contains a considerable number of pores, and 1 g of **X** can accommodate  $3.0 \times 10^2 \text{ mL}$  of  $\text{CO}_2$  gas in the pores at 1 bar and  $25^\circ\text{C}$ . **Calculate** the average number of  $\text{CO}_2$  molecules per pore. 5pt

Eldfjall á Sakurajima eyju

### Part A

Japan er eitt þeirra landa í heiminum sem hefur flest eldfjöll. Þegar silíkatasteindir kristallast frá hraunkviku þá fer hluti af hliðarmálmjónum ( $M^{n+}$ ) úr hraunkvikunni í silikatsteindirnar. Í þessu dæmi eru  $M^{n+}$  jónir girtar (coordinated) oxíðjónum ( $O^{2-}$ ) með fjörtengdri tetrahedral ( $T_d$ ) byggingu í hraunkvikunni og sextengdri oktahdral ( $O_h$ ) byggingu í silíkateindum. Í bæði  $T_d$  og  $O_h$  byggingum hafa  $M^{n+}$  jónirnar háspuna rafeindaskipan. Dreifingarstuðullinn fyrir  $M^{n+}$  milli silíkateinda og kvíkubráðar,  $D$ , er gefinn með eftirfarandi jöfnu:

$$D = \frac{[M]_s}{[M]_l}$$

þar sem  $[M]_s$  styrkur  $M^{n+}$  í silíkateindum og  $[M]_l$  er styrkur  $M^{n+}$  í hraunkvikunni. Í töflunni hér að neðan eru gefin dæmi um gildi  $D$  fyrir  $Cr^{2+}$  og  $Mn^{2+}$ .

	$Cr^{2+}$	$Mn^{2+}$
$D$	7.2	1.1

Látum  $\Delta_O$  vera orkumun d-svigrúma  $M^{n+}$  og  $CFSE^O$  vera kristalsviðsorkuna (the crystal-field stabilization energy) í  $O_h$  sviði. Látum  $\Delta_T$  og  $CFSE^T$  vera samsvarandi stærðir fyrir  $T_d$  svið.

**A.1**

6pt

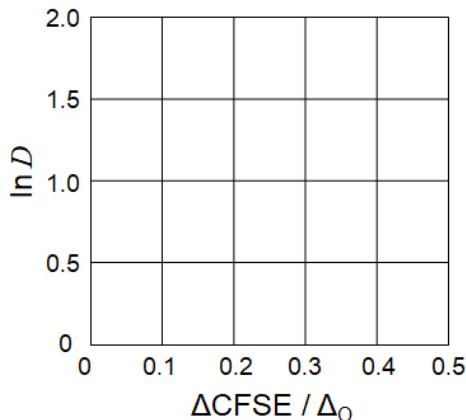

**Reiknaðu**  $|CFSE^O - CFSE^T| = \Delta CFSE$  miðað við  $\Delta_O$  fyrir  $Cr^{2+}$ ,  $Mn^{2+}$  og  $Co^{2+}$ ; gerðu ráð fyrir að  $\Delta_T = 4/9\Delta_O$ .

**A.2**

3pt

Línulegt samband kemur fram á grafi þegar  $\ln D$  er teiknað á móti  $\Delta CFSE / \Delta_O$  í hnitakerfinu hér fyrir neðan.

**Reiknaðu gildi**  $D$  fyrir  $Co^{2+}$ .

Málmoxíð MO (M: Ca, Ti, V, Mn eða Co) hafa samskonar kristalbyggingu og matarsalt þar sem  $M^{n+}$  er í  $O_h$  umhverfi og með háspuna rafeindaskipan. Grindarorka þessara oxíða er aðalega vegna Coulombkrafta á milli jóna, en þeir ráðast af radíus og hleðslu jónanna, auk dálítils framlags frá CFSE fyrir  $M^{n+}$  í  $O_h$  sviði.

**A.3**

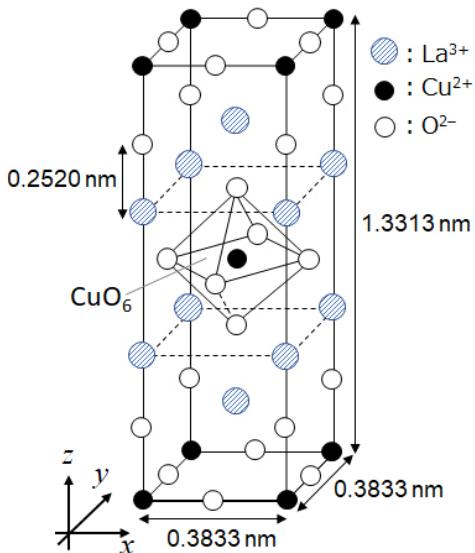

3pt

**Veldu** viðeigandi röð (a) til (f) fyrir grindarorku [ $\text{kJ mol}^{-1}$ ] málmoxíðanna.

	<b>CaO</b>	<b>TiO</b>	<b>VO</b>	<b>MnO</b>	<b>CoO</b>

<b>(d)</b>	3810	3878	3913	3460	3916
<b>(e)</b>	3810	3916	3878	3460	3913
<b>(f)</b>	3810	3913	3916	3460	3878

**Part B**

Blandað oxíð **A**, sem inniheldur  $\text{La}^{3+}$  og  $\text{Cu}^{2+}$ , kirstallast með tetragonal grindareiningu eins og sýnt er á mynd 1. Í  $[\text{CuO}_6]$  oktahedronum er  $\text{Cu}-\text{O}$  lengdin eftir  $z$ -ásnum ( $l_z$ ) lengri en sú sem er á  $x$ -ásnum ( $l_x$ ).  $[\text{CuO}_6]$  er því bjagað frá reglulegri  $O_h$  byggingu og hverfur þá margfeldni (degeneracy)  $e_g$  svigrúmanna ( $d_{x^2-y^2}$  og  $d_{z^2}$ ).

Mynd 1

**A** er búið til með því að hitarjúfa (pyrolysis) komplex **B**. **B** er búið til með því að blanda saman málmkloríðum í þynntri ammoníks vantlausn sem inniheldur squariksýru  $\text{C}_4\text{H}_2\text{O}_4$ , en hún er tvísýra. Þegar **B** er hitað upp í  $200^\circ\text{C}$  í þurru loftar tapar það 29,1% af massa sínum vegna uppgufunar kristalvatns (crystallization water), og ef það er hitað áfram upp í  $700^\circ\text{C}$  þá rofnar  $\text{CO}_2$  frá efninu. Heildarmassatapið við myndun **A** frá **B** er 63,6%. Bent skal á að aðeins vatn og  $\text{CO}_2$  rjúka burt við hitarofshvarfið.

**B.1**

6pt

Ritaðu efnaformúlur **A** og **B**.

**B.2**

4pt

Reiknaðu  $l_x$  og  $l_z$  frá mynd 1.

**B.3**

4pt

Ritaðu nöfn klofnu  $e_g$  svigrúmanna ( $d_{x^2-y^2}$  og  $d_{z^2}$ ) í (i) og (ii) fyrir  $\text{Cu}^{2+}$  bjagaða  $[\text{CuO}_6]$  oktahedroninn í **A** á mynd 1 og teiknaðu rafeindaskipanina í punktsrik-  
uðu reitina á svarblaðinu þínu.

**A** er rafeinangrandi efni. Þegar einu  $\text{La}^{3+}$  er skipt út fyrir eitt  $\text{Sr}^{2+}$ , þá myndast ein hola í kristagrindinni sem getur leitt rafmagn. **A** sem íbætt (doped) er með  $\text{Sr}^{2+}$  verður þá ofurleiðandi fyrir neðan 38 K. Þegar slíkt skiptihvarf var framkvæmt fyrir **A** þá mynduðust  $2,05 \times 10^{27}$  holur á  $\text{m}^3$ .

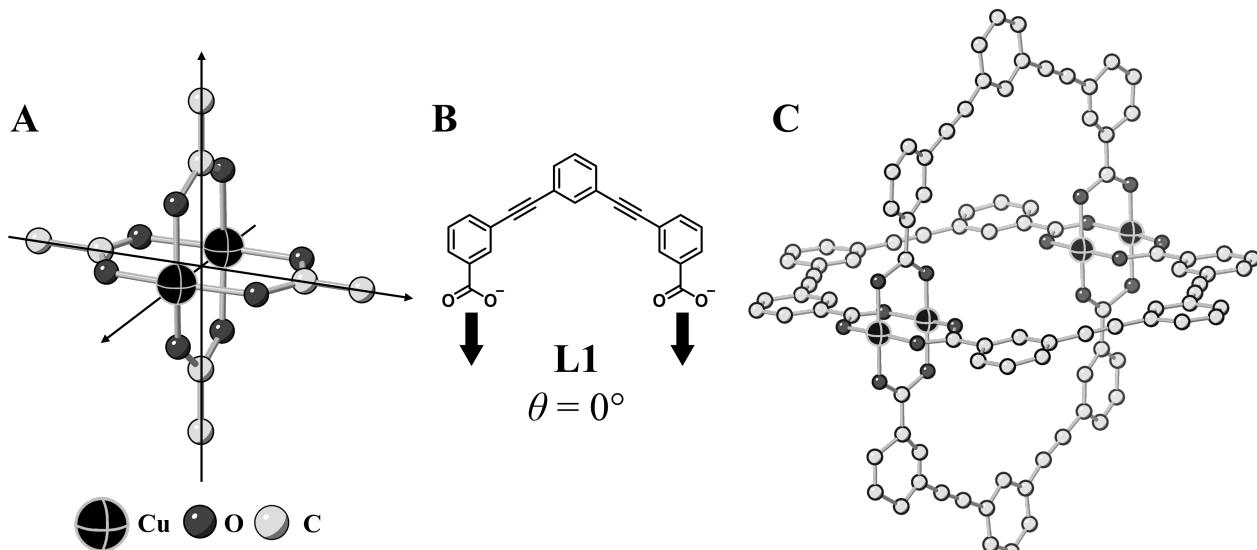

B.4

4pt

**Reiknaðu** prósentuna af  $\text{Sr}^{2+}$  sem skipt var út fyrir  $\text{La}^{3+}$  frá móhlutfallinu í skiptihvarfinu. Athugaðu að hleðsla jónanna og kristalbyggingin breytast ekki við skiptihvarfið.

## Hluti C

$\text{Cu}_2(\text{CH}_3\text{CO}_2)_4$  er samsett úr  $\text{CH}_3\text{CO}_2^-$  sem tengjast tveimur  $\text{Cu}^{2+}$  (mynd 2A). Bygging  $\text{Cu}_2(\text{CH}_3\text{CO}_2)_4$  hefur mikla samhverfu (symmetry) þar sem tveir ásar fara í gegnum kolefnisatóm fjögurra  $\text{CH}_3\text{CO}_2^-$  auk áss sem fer í gegnum tvö  $\text{Cu}^{2+}$ , en ásarnir þrír eru hornréttir hver á annan. Þegar díkarboxýlat tengill (ligand) er notaður í stað  $\text{CH}_3\text{CO}_2^-$ , myndast "búrkomplex" ("cage complex"). Búrkomplexinn  $\text{Cu}_4(\text{L1})_4$  er samsettur úr flötu díkarboxýlati **L1** (mynd 2B) og  $\text{Cu}^{2+}$  (mynd 2C). Bygging búrkomplexins ákvaðast af horninu  $\theta$  milli girðistefnu (coordination directions) karboxýlathópanna tveggja, en  $\theta$ -hornið sem er sýnt með örjunum á mynd 2B. Gildi  $\theta$  er  $0^\circ$  fyrir **L1**. Athugaðu að vetrnisatómin eru ekki sýnd á mynd 2.

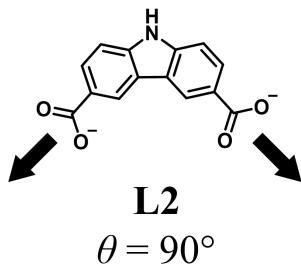

Mynd 2

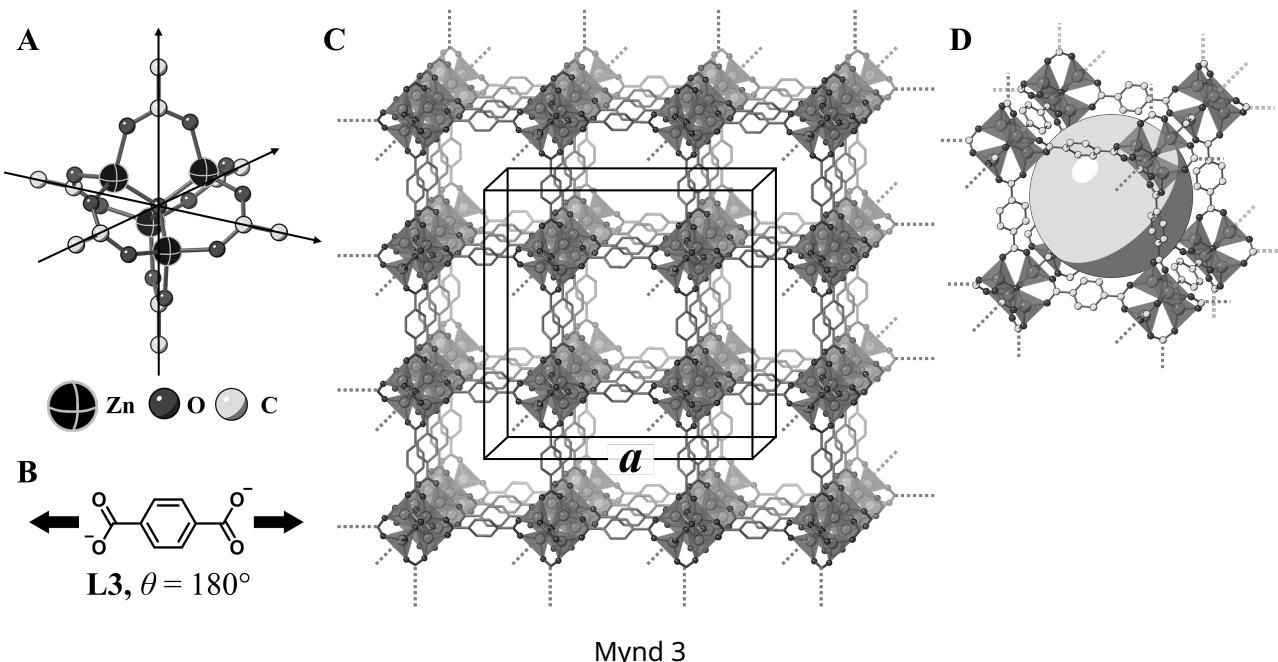

C.1

5pt

Hornið  $\theta$  fyrir flata díkarboxýlatið **L2** hér að neðan helst fast við  $90^\circ$ . **Ákvaðaðu** minnstu gildin fyrir  $n$  og  $m$  ef samsetning búrkomplexins sem myndast frá **L2** og  $\text{Cu}^{2+}$  er  $\text{Cu}_n(\text{L2})_m$ . Gerðu ráð fyrir að aðeins  $\text{CO}_2^-$  hópar **L2** tengist  $\text{Cu}^{2+}$  jónum.

Zinkkomplex,  $\text{Zn}_4\text{O}(\text{CH}_3\text{CO}_2)_6$ , inniheldur fjögur  $\text{Zn}^{2+}$  sem mynda tetrahedral-laga klasa, ásamt sex  $\text{CH}_3\text{CO}_2^-$  og einu  $\text{O}^{2-}$  (mynd 3A). Í  $\text{Zn}_4\text{O}(\text{CH}_3\text{CO}_2)_6$  er  $\text{O}^{2-}$  í miðjunni og þrír ásar fara í gegnum kolefnisatóm  $\text{CH}_3\text{CO}_2^-$  og eru þeir hornréttir hver á annan. Þegar *p*-benzenedíkarboxýlat (mynd 3B, **L3**,  $\theta = 180^\circ$ ) er notað í stað  $\text{CH}_3\text{CO}_2^-$ , tengjast  $\text{Zn}^{2+}$  klasarnir sama í kristallað fast efni (**X**) sem kallast "gljúp girðifjölliða" ("porous coordination polymer", mynd 3C). Samsetning **X** er  $[\text{Zn}_4\text{O}(\text{L3})_3]_n$ , og hefur efnið teningsлага kristalbyggingu með holur af nanóstærð. Ein slík nanóhola er sýnd sem kúla á mynd 3D og er hver tetrahedral-laga  $\text{Zn}^{2+}$  klasi táknaður sem dökkgrár fjölfötungur á myndum 3C og 3D. Athugaðu að vetrnisatómin eru ekki sýnd á mynd 3.

**C.2**

5pt

**X** hefur teningslaga grindareiningu með kantlengdina  $a$  (mynd 3C) og eðlis-massann  $0,592 \text{ g cm}^{-3}$ . **Reiknaðu** meðalfjölda  $\text{CO}_2$  sameinda sem eru í hverri nanóholu.

**C.3**

5pt

**X** inniheldur aragrúa fjölda nanóhola og 1 g af **X** getur hýst  $3,0 \times 10^2 \text{ mL}$  af  $\text{CO}_2$  sem er við 1 bar og  $25^\circ\text{C}$ . **Reiknaðu** meðalfjölda  $\text{CO}_2$  sameinda sem eru í hverri nanóholu.

### Part A

Linearifolianone is a natural product with a unique structure, which was isolated from *Inula linariifolia*. From valencene (**1**), a one-step conversion yields **2**, before a three-step conversion via **3** yields ketone **4**. Eremophilene (**5**) is converted into **6** by performing the same four-step conversion.

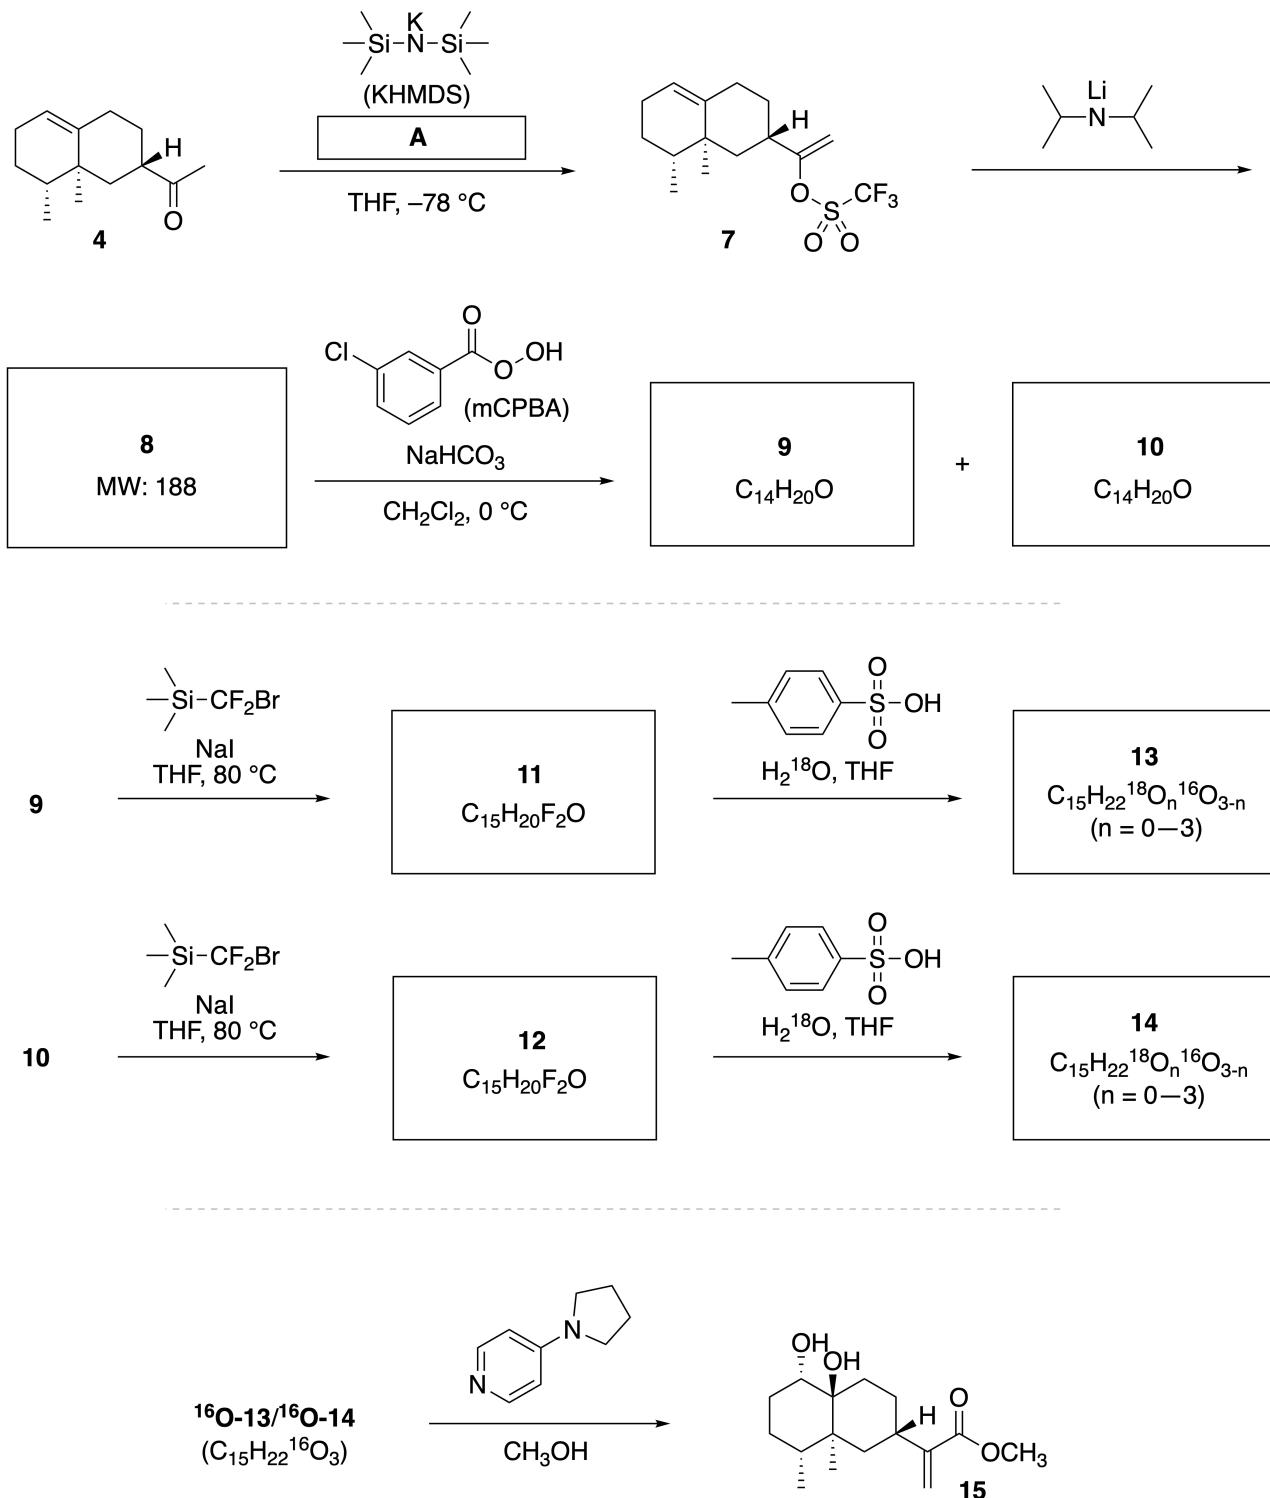

*Inula linariifolia*

**A.1** Draw the structures of **2** and **6** and clearly identify the stereochemistry where necessary. 5pt

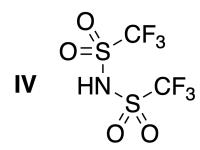

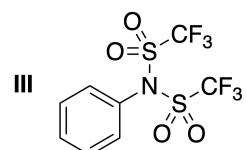

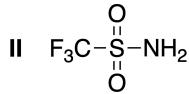

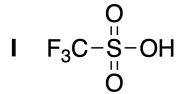

Then, ketone **4** is converted into ester **15**. Compound **8** (molecular weight: 188) retains all the stereocenters in **7**. Compounds **9** and **10** have five stereocenters and no carbon-carbon double bonds. Assume

that  $\text{H}_2^{18}\text{O}$  is used instead of  $\text{H}_2^{16}\text{O}$  for the synthesis of  $^{18}\text{O}$ -labelled-lineariifolianones **13** and **14** from **11** and **12**, respectively. Compounds **13** and **14** are  $^{18}\text{O}$ -labelled isotopomers. Ignoring isotopic labelling, both **13** and **14** provide the same product **15** with identical stereochemistry.

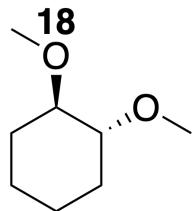

**A.2** Choose the appropriate structure for A.

2pt

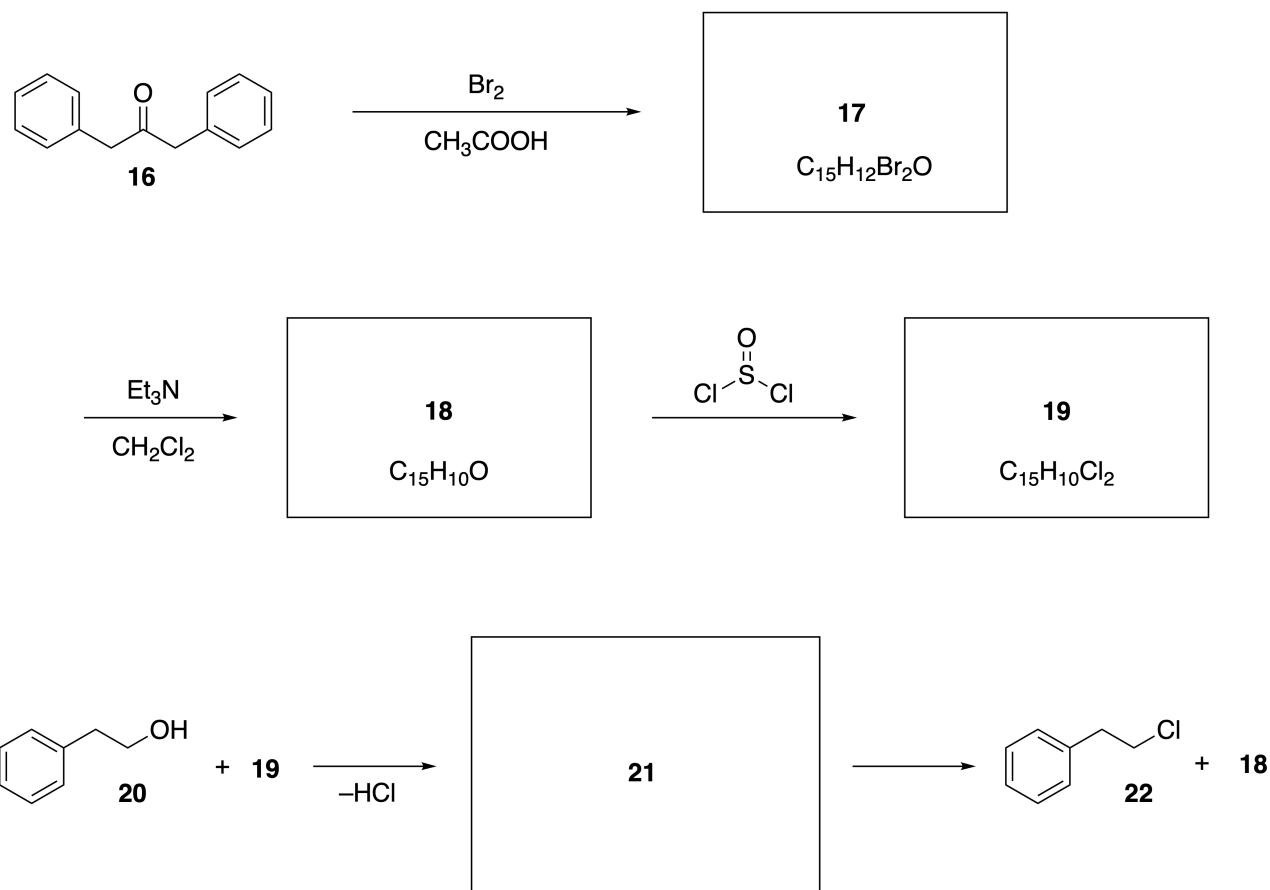

**A.3** Draw the structures of **8–14** and clearly identify the stereochemistry where necessary. Also, indicate the introduced  $^{18}\text{O}$  atoms for **13** and **14** as shown in the example below. 19pt

**Part B**

Compound **19** is synthesized as shown below. In relation to non-benzenoid aromaticity, **19** can be used as an activator for alcohols, and **20** was converted to **22** via ion-pair intermediate **21**. Although the formation of **21** was observed by NMR, **21** gradually decomposes to give **18** and **22**.

<sup>1</sup>H NMR (CD<sub>3</sub>CN, ppm)   **20**:  $\delta$  7.4–7.2 (5H), 3.7 (2H), 2.8 (2H), 2.2 (1H)  
**21**:  $\delta$  8.5–7.3 (15H), 5.5 (2H), 3.4 (2H)

**B.1** Draw the structures of **17–19** and **21**. Identifying the stereochemistry is not necessary. 10pt

## Dynamic Organic Molecules and Their Chirality

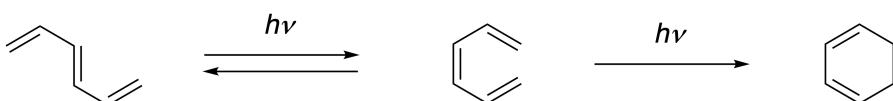

11 % of the total						
Question	A.1	A.2	A.3	B.1	B.2	Total
Points	9	3	7	3	4	<b>26</b>
Score						

### Part A

Polycyclic aromatic hydrocarbons with successive ortho-connections are called [n]carbohelicenes (here, n represents the number of six-membered rings) (see below). [4]Carbohelicene (**[4]C**) is efficiently prepared by a route using a photoreaction as shown below, via an intermediate (**Int.**) that is readily oxidized by iodine.

The photoreaction proceeds in a manner similar to the following example.

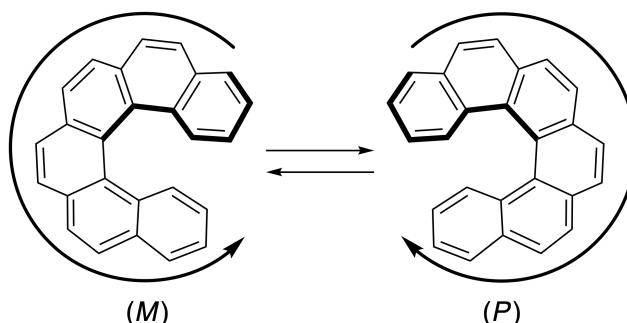

**Note: For all of Question 8, please draw alternating single and double bonds in your answers to the problems as depicted in the examples of carbohelicene. Do not use circles for conjugated  $\pi$  systems.**

**A.1** Draw the structures of **A-C**. Stereoisomers should be distinguished. 9pt

**A.2** Attempts to synthesize [5]carbohelicene from the same phosphonium salt and an appropriate starting compound resulted in the formation of only a trace amount of [5]carbohelicene, instead affording product **D** whose molecular weight was 2 Da lower than that of [5]carbohelicene. The  $^1\text{H}$  NMR chemical shifts of **D** are listed below. Draw the structure of **D**.

[**D** ( $\delta$ , ppm in  $\text{CS}_2$ , r.t.), 8.85 (2H), 8.23 (2H), 8.07 (2H), 8.01 (2H), 7.97 (2H), 7.91 (2H)]

[5]- and larger [n]carbohelicenes have helical chirality and interconversion between enantiomers of these helicenes is significantly slow at room temperature. The chirality of [n]carbohelicenes is defined as (M) or (P) as shown below.

[n]Carbohelicenes with n larger than 4 can be enantiomerically separated by a chiral column chromatography, which was developed by Prof. Yoshio Okamoto.

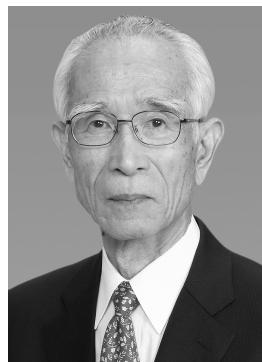

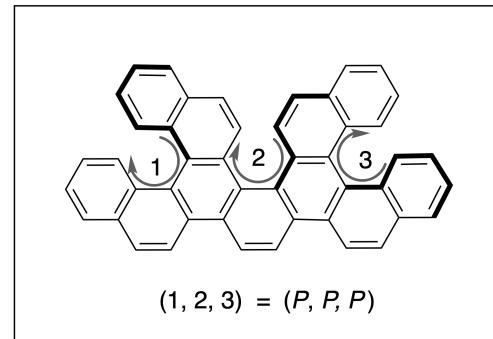

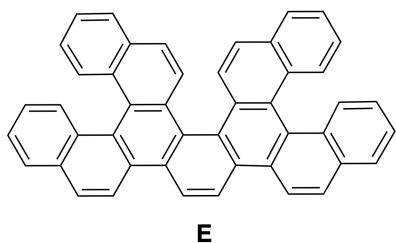

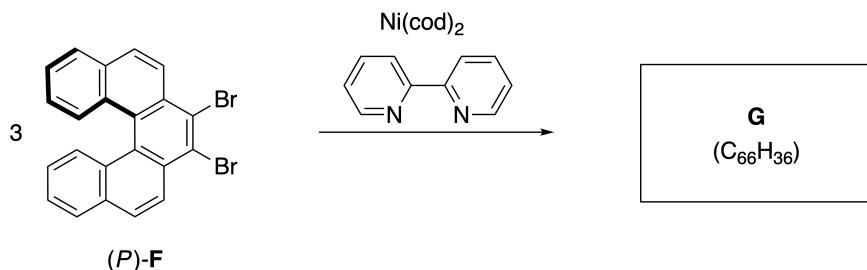

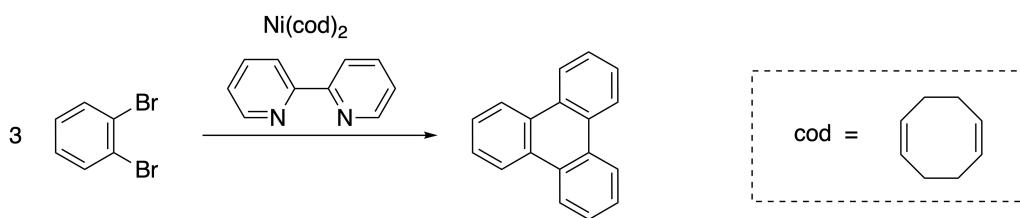

Photo courtesy: The Japan Prize Foundation

Multiple helicenes are molecules that contain two or more helicene-like structures. If its helical chirality is considered, several stereoisomers exist in a multiple helicene. For example, compound **E** contains three [5]carbohelicene-like moieties in one molecule. One of the stereoisomers is described as  $(P, P, P)$  as shown below.

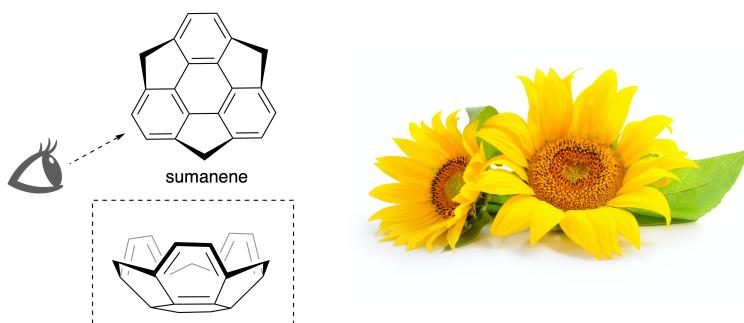

- A.3** The nickel-mediated trimerization of 1,2-dibromobenzene generates triphenylene. When the same reaction is applied to an enantiomer of **F**,  $(P)$ -**F**, multiple helicene **G** ( $C_{66}H_{36}$ ) is obtained. Given that interconversion between stereoisomers does not occur during the reaction, **identify all** the possible stereoisomers of **G** formed in this process, without duplication. As a reference, one isomer should be drawn completely with the chirality defined as in the example above, with numerical labels; the other stereoisomers should be listed with location numbers and *M* and *P* labels according to the same numbering. For instance, the other stereoisomers of **E** should be listed as  $(1, 2, 3) = (P, M, P), (P, M, M), (P, P, M), (M, M, M), (M, M, P), (M, P, P)$ , and  $(M, P, M)$ . 7pt

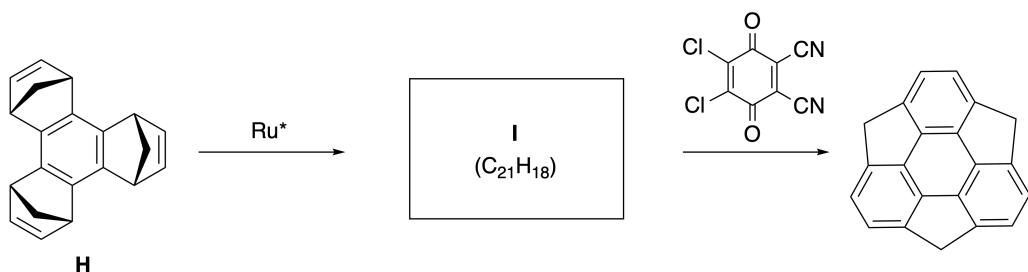

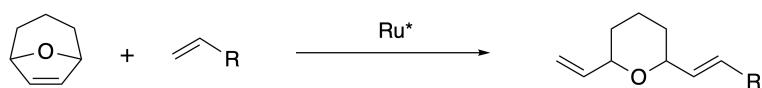

**Part B**

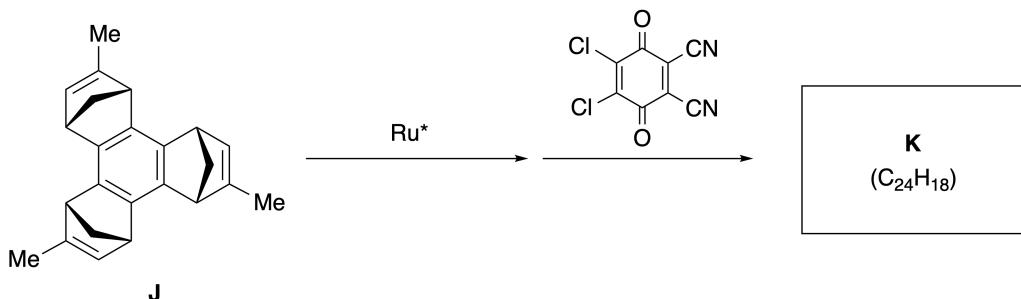

Sumanene is a bowl-shaped hydrocarbon that was first reported in Japan in 2003. The name "sumanene" derives from a Sanskrit-Hindi word "suman" that means sunflower. The synthesis of sumanene was achieved by a reaction sequence that consists of a ring-opening and a ring-closing metathesis.

Representative metathesis reactions catalyzed by a ruthenium catalyst ( $\text{Ru}^*$ ) are shown below.

- B.1** Draw the structure of intermediate **I** (its stereochemistry is not required). 3pt

- B.2** Starting from the optically active precursor **J**, the same reaction sequence gives the optically active sumanene derivative **K**. The stereocenters in **J** suffer no inversion during the metathesis reaction. Draw the structure of **K** with the appropriate stereochemistry. 4pt

Good kids don't do this, but if you unseam a tennis ball, you can disassemble it into two U-shaped pieces.

Based on this idea, compounds **1** and **2** were synthesized as U-shaped molecules with different sizes. Compound **3** was prepared as a comparison of **1** and the encapsulation behavior of these compounds was investigated.

The synthetic route to **2** is shown below. The elemental composition of compound **9**: C; 40.49%, H; 1.70%, and O; 17.98% by mass.

- A.1** **Draw** the structures of **4–9**; the stereochemistry can be neglected. Use "PMB" 13pt as a substituent instead of drawing the whole structure of *p*-methoxybenzyl group shown in the scheme above.

In the mass spectrum of **1**, the ion peak corresponding to its dimer (**1<sub>2</sub>**) was clearly observed, whereas an ion peak for **3<sub>2</sub>** was not observed in the spectrum of **3**. In the <sup>1</sup>H NMR spectra of a solution of **1<sub>2</sub>**, all the NH protons derived from **1** were observed to be chemically equivalent, and their chemical shift was significantly different from that of the NH protons of **3**. These data indicate that hydrogen bonds are formed between the NH moieties of **1** and atoms **X** of another molecule of **1** to form the dimeric capsule.

- A.2** **Circle** all the appropriate atom(s) **X** in **1**. 2pt

- A.3** **Give** the number of the hydrogen bonds in the dimeric capsule (**1<sub>2</sub>**). 2pt

The dimeric capsule of **1** (**1**<sub>2</sub>) has an internal space wherein an appropriate small molecule Z can be encapsulated. This phenomenon is expressed by the following equation:

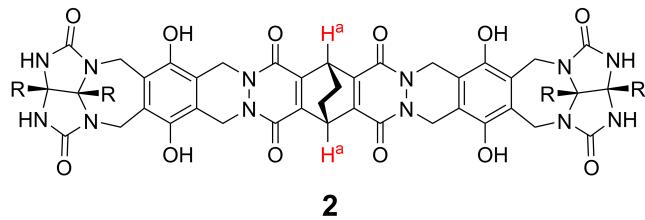

The equilibrium constant of the encapsulation of Z into **1**<sub>2</sub> is given as below:

$$K_a = \frac{[Z@\mathbf{1}_2]}{[Z][\mathbf{1}_2]} \quad (2)$$

Encapsulation of a molecule into a capsule could be monitored by NMR spectroscopy. For example, **1**<sub>2</sub> in C<sub>6</sub>D<sub>6</sub> gave different signals in the <sup>1</sup>H NMR spectra before and after addition of CH<sub>4</sub>.

Compound **2** also forms a rigid and larger dimeric capsule (**2**<sub>2</sub>). The <sup>1</sup>H NMR spectrum of **2**<sub>2</sub> was measured in C<sub>6</sub>D<sub>6</sub>, C<sub>6</sub>D<sub>5</sub>F, and a C<sub>6</sub>D<sub>6</sub>/C<sub>6</sub>D<sub>5</sub>F solvent mixture, with all other conditions being kept constant. The chemical shifts for the H<sup>a</sup> proton of **2** in the above solvents are summarized below, and no other signals from the H<sup>a</sup> in **2**, except for the listed, were observed. Assume that the interior of the capsule is always filled with the largest possible number of solvent molecules and that each signal corresponds to one species of the filled capsule.

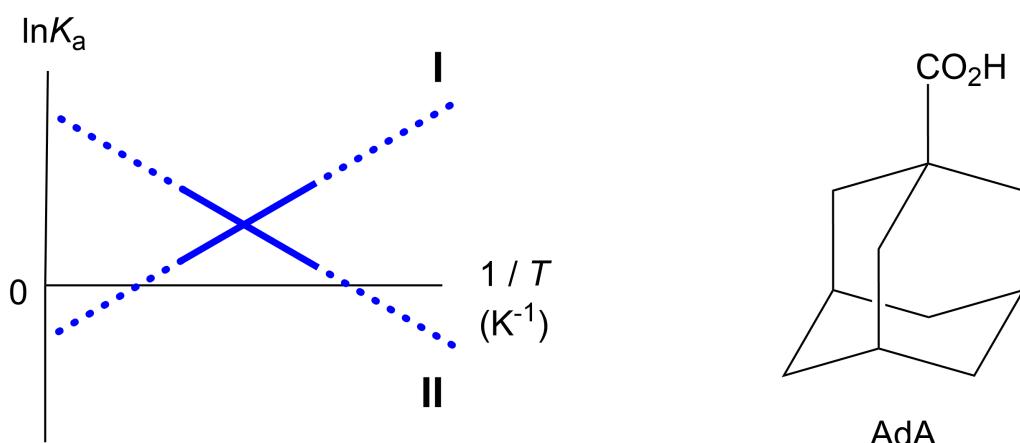

solvent	$\delta$ (ppm) of H <sup>a</sup>
C <sub>6</sub> D <sub>6</sub>	4.60
C <sub>6</sub> D <sub>5</sub> F	4.71
C <sub>6</sub> D <sub>6</sub> / C <sub>6</sub> D <sub>5</sub> F	4.60, 4.71, 4.82

**A.4** **Determine** the number of C<sub>6</sub>D<sub>6</sub> and C<sub>6</sub>D<sub>5</sub>F molecules encapsulated in **2**<sub>2</sub> giving 3pt each H<sup>a</sup> signal.

$^1\text{H}$  NMR measurements in  $\text{C}_6\text{D}_6$  revealed that  $\mathbf{2}_2$  can incorporate one molecule of 1-adamantanecarboxylic acid (AdA), and the association constants ( $K_a$ ) which are expressed below were determined for various temperatures.  $[\text{solvent}@\mathbf{2}_2]$  denotes a species containing one or more solvent molecules.

$$K_a = \frac{[\text{Z}@\mathbf{2}_2]}{[\text{Z}][\text{solvent}@\mathbf{2}_2]} \quad (3)$$

Similarly, the  $K_a$  values of  $\text{CH}_4$  and  $\mathbf{1}_2$  given as eq (2) at various temperatures in  $\text{C}_6\text{D}_6$  were also determined by  $^1\text{H}$  NMR measurements. The plots of the two association constants (as  $\ln K_a$  vs  $1/T$ ) are shown below.

No  $\text{C}_6\text{D}_6$  molecule is encapsulated in  $\mathbf{1}_2$ . In line **II**, the entropy change ( $\Delta S$ ) is ( 1 ) and enthalpy change ( $\Delta H$ ) is ( 2 ), indicating that the driving force for the encapsulation in line **II** is ( 3 ). Therefore, line **I** corresponds to ( 4 ), and line **II** corresponds to ( 5 ).

**A.5** Choose the correct options in gaps (1)-(5) in the following paragraph from A 3pt and B.

	A	B
(1)	positive	negative
(2)	positive	negative
(3)	$\Delta S$	$\Delta H$
(4)	$\mathbf{1}_2$ and $\text{CH}_4$	$\mathbf{2}_2$ and AdA
(5)	$\mathbf{1}_2$ and $\text{CH}_4$	$\mathbf{2}_2$ and AdA
