NZL-1 C-0 G-1

International Chemistry Olympiad 2021 Japan 53rd IChO2021 Japan 25th July – 2nd August, 2021 https://www.icho2021.org NZL English Version

General Instruction

- You are only allowed to use pen to write answers.
- Your calculator must be non-programmable.
- This examination has **9 problems**.
- You can solve the problems in any order.
- You will have **5 hours** to solve all problems.
- You can **begin** working only after the **START** command is given.
- All results must be written in the appropriate answer boxes with pen on the **answer sheets**. Use the back of the question sheets if you need paper for working. Remember that answers written outside the answer boxes will not be graded.
- You must write relevant calculations in the appropriate boxes when necessary. Full marks will only be given for correct answers when your work is shown.
- The invigilator will announce a **30-minute** warning before the **STOP** command.
- You **must stop** working when the **STOP** command is given. Failure to stop writing will lead to the nullification of your examination.
- The official English version of this examination is available on request for clarification.
- You are not allowed to leave your working place without permission. If you need any assistance (e.g., broken calculator, need to visit a restroom), raise your hand and wait until an invigilator arrives.

GOOD LUCK!

Hydrogen at a Metal Surface

	11 % of the total						
Question	A.1	A.2	B.1	B.2	B.3	B.4	Total
Points	6	4	5	3	3	3	24
Score							

NZL-1 C-1 Q-1

Hydrogen is expected to be a future energy source that does not depend on fossil fuels. Here, we will consider the hydrogen-storage process in a metal, which is related to hydrogen-transport and -storage technology.

Part A

As hydrogen is absorbed into the bulk of a metal via its surface, let us first consider the *adsorption* process of hydrogen at the metal surface, $H_2(g) \rightarrow 2H(ad)$, where the gaseous and adsorbed states of hydrogen are represented as (g) and (ad), respectively.

Hydrogen molecules (H₂) that reach the metal surface (M) dissociate at the surface and are adsorbed as H atoms (*Fig. 1*). Here, the potential energy of H₂ is represented by two variables: the distance between the hydrogen atoms, d, and the height relative to the surface metal atom, z. It is assumed that the axis along the two H atoms is parallel to the surface and that the centre of mass is always on the vertical dotted line in *Fig. 1*.

Fig. 2 shows the potential energy contour plot for the dissociation at the surface. The numerical values on the graph represent the potential energy in units of kJ per mole of H_2 . The solid line spacing is 20 kJ mol⁻¹, the dashed line spacing is 100 kJ mol⁻¹, and the spacing between solid and dashed lines is 80 kJ mol⁻¹. The zero-point vibration energy is ignored.

NZL-1 C-1 Q-2

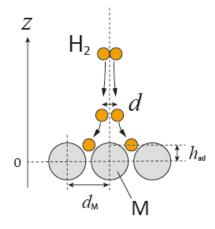

Fig.1 Definition of variables. Drawing is not in scale.

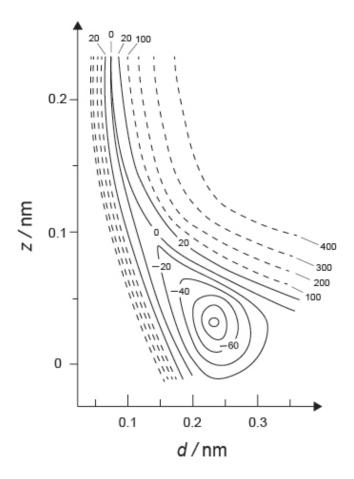

Fig.2 Potential energy contour plot for the dissociation at the surface

A.1For each of the following items (i)–(iii), select
(ii) The interatomic distance for a gaseous H_2 molecule
(ii) The interatomic distance between metal atoms (d_M in Fig. 1)
(iii) The distance of adsorbed H atoms from the surface (h_{ad} in Fig. 1)6ptA. 0.03 nmB. 0.07 nmC. 0.11 nmD. 0.15 nm

A. 0.03 nm B. 0.07 nm C. 0.11 nm D. 0.15 nm E. 0.19 nm F. 0.23 nm G. 0.27 nm

A.2 For each of the following items (i)–(ii), <u>select</u> the closest value from A–H. (i) the energy required for the dissociation of gaseous H₂ to gaseous H $[H_2(g) \rightarrow 2H(g)]$ (ii) the energy released during the adsorption of a gaseous H₂ $[H_2(g) \rightarrow 2H(ad)]$ A. 20 kJ mol⁻¹ B. 40 kJ mol⁻¹ C. 60 kJ mol⁻¹ D. 100 kJ mol⁻¹ E. 150 kJ mol⁻¹ F. 200 kJ mol⁻¹ G. 300 kJ mol⁻¹ H. 400 kJ mol⁻¹

NZL-1 C-1 Q-4

Part B

The adsorbed hydrogen atoms are then either absorbed into the bulk, or recombine and desorb back into the gas phase, as shown in the reactions (1a) and (1b). H(ab) represents a hydrogen atom absorbed in the bulk.

$$H_2(g) \stackrel{k_1}{\underset{k_2}{\longleftrightarrow}} 2H(ad)$$
(1a)

$$H(ad) \xrightarrow{k_3} H(ab)$$
(1b)

The reaction rates per surface site for adsorption, desorption, and absorption are $r_1[s^{-1}], r_2[s^{-1}]$ and $r_3[s^{-1}]$, respectively. They are expressed as:

$$r_1 = k_1 P_{\mathsf{H}_2} (1 - \theta)^2 \tag{2}$$

$$r_2 = k_2 \theta^2 \tag{3}$$

$$r_3 = k_3 \theta \tag{4}$$

where $k_1 [s^{-1} Pa^{-1}]$, $k_2 [s^{-1}]$ and $k_3 [s^{-1}]$ are the reaction rate constants and P_{H_2} is the pressure of H_2 . Among the sites available on the surface, θ ($0 \le \theta \le 1$) is the fraction occupied by H atoms.

It is assumed that adsorption and desorption are fast compared to absorption ($r_1, r_2 \gg r_3$) and that θ remains constant.

B.1 r_3 can be expressed as: 5pt $r_3 = \frac{k_3}{1 + \sqrt{\frac{1}{P_{H_2}C}}}$ (5) **Express** C using k_1 and k_2 .

A metal sample with a surface area of $S = 1.0 \times 10^{-3} \text{ m}^2$ was placed in a container (1L = $1.0 \times 10^{-3} \text{ m}^3$) with H₂ ($P_{\text{H}_2} = 1.0 \times 10^2 \text{ Pa}$).

The number of hydrogen-atom adsorption sites per unit area on the surface was $N=1.3 imes 10^{18}\,{
m m}^{-2}$.

The surface temperature was kept at T = 400 K.

As the reaction (1) proceeded, $P_{\rm H_2}$ decreased at a constant rate of $v = 4.0 \times 10^{-4} \, {\rm Pa \ s^{-1}}$.

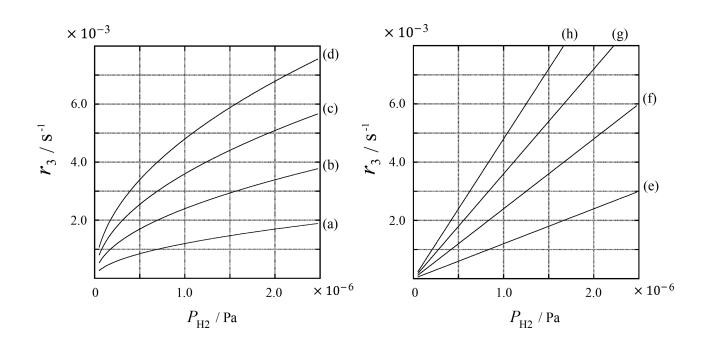

Assume that H_2 is an ideal gas and that the volume of the metal sample is negligible.

B.3 At T = 400 K, C equals 1.0×10^2 Pa⁻¹. <u>Calculate</u> the value of k_3 at 400 K. If you did not obtain the answer to **B.2**, use $A = 3.6 \times 10^{-7}$ mol s⁻¹ m⁻².

3pt

B.4 At a different T, $C = 2.5 \times 10^3 \text{ Pa}^{-1}$ and $k_3 = 4.8 \times 10^{-2} \text{ s}^{-1}$ are given. For r_3 as a generative function of P_{H_2} at this temperature, **select** the correct plot from (a)–(h).

NZL-1 C-2 Q-1

Isotope Time Capsule

11 % of the total						
Question	A.1	A.2	A.3	A.4	Total	
Points	8	8	10	9	35	
Score						

Molecular entities that differ only in isotopic composition, such as CH_4 and CH_3D , are called *isotopologues*. Isotopologues are considered to have the same chemical characteristics. In nature, however, there exists a slight difference.

Assume that all of the substances shown in this Question are in a gas phase.

Let us consider the following equilibrium:

$${}^{12}\mathsf{C}^{16}\mathsf{O}_2 + {}^{12}\,\mathsf{C}^{18}\mathsf{O}_2 \rightleftharpoons 2^{12}\mathsf{C}^{16}\mathsf{O}^{18}\mathsf{O} \qquad \qquad K = \frac{[{}^{12}\mathsf{C}^{16}\mathsf{O}^{18}\mathsf{O}]^2}{[{}^{12}\mathsf{C}^{16}\mathsf{O}_2][{}^{12}\mathsf{C}^{18}\mathsf{O}_2]} \tag{1}$$

The entropy, *S*, increases with increasing the number of possible microscopic states of a system, *W*:

$$S = k_{\mathsf{B}} \ln W \tag{2}$$

W = 1 for ${}^{12}C^{16}O_2$ and ${}^{12}C^{18}O_2$.

In contrast, W = 2 for a ${}^{12}C^{16}O^{18}O$ molecule because the oxygen atoms are distinguishable in this molecule. As the right-hand side of the equilibrium shown in eq. 1 has two ${}^{12}C^{16}O^{18}O$ molecules, $W = 2^2 = 4$.

A.1 The enthalpy change,
$$\Delta H$$
, of eq. 3 is positive regardless of the temperature. 8pt
 $H_2 + DI \rightleftharpoons HD + HI$ (3)

<u>**Calculate**</u> the equilibrium constants, K, for eq. 3 at very low (think of $T \rightarrow 0$) and very high (think of $T \rightarrow +\infty$) temperatures. Assume that the reaction remains unchanged at these temperatures and that ΔH converges to a constant value for high temperatures.

The ΔH of the following process can be explained by molecular vibrations.

$$2\mathsf{H}\mathsf{D} \rightleftharpoons \mathsf{H}_2 + \mathsf{D}_2 \qquad \qquad K = \frac{[\mathsf{H}_2][\mathsf{D}_2]}{[\mathsf{H}\mathsf{D}]^2} \tag{4}$$

At T = 0 K, the vibrational energy of a diatomic molecule whose vibration frequency is ν [s⁻¹] is expressed as:

$$E = \frac{1}{2}h\nu$$
(5)

$$\nu = \frac{1}{2\pi} \sqrt{\frac{k}{\mu}} \tag{6}$$

Wherein k is the force constant and μ the reduced mass, which is expressed in terms of the mass of the two atoms in the diatomic molecule, m_1 and m_2 , according to:

$$\mu = \frac{m_1 m_2}{m_1 + m_2} \tag{7}$$

A.2 The vibration of H₂ is at 4161.0 cm⁻¹ when reported as a wavenumber. 8pt <u>**Calculate**</u> the ΔH of the following equation at T = 0 K in units of J mol⁻¹.

$$2HD \rightarrow H_2 + D_2 \tag{8}$$

Assume that:

- only the vibrational energy contributes to the $\Delta H.$
- the k values for H₂, HD, and D₂ are identical.
- the mass of H to be 1 Da and the mass of D to be 2 Da.

The molar ratio of H₂, HD, and D₂ depends on the temperature in a system in equilibrium. Here, Δ_{D_2} is defined as the change of the molar ratio of D₂.

$$\Delta_{\mathsf{D}_2} = \frac{R_{\mathsf{D}_2}}{R_{\mathsf{D}_2}^*} - 1 \tag{9}$$

Here, R_{D_2} refers to $\frac{[D_2]}{[H_2]}$ in the sample and $R_{D_2}^*$ to $\frac{[D_2]}{[H_2]}$ at $T \to +\infty$. It should be noted here that the distribution of isotopes becomes random at $T \to +\infty$.

A.3 **Calculate**
$$\Delta_{D_2}$$
 with natural D abundance when the isotopic exchange is in equi-
librium at the temperature where *K* in eq. 4 is 0.300.
Assume that the natural abundance ratios of D and H are 1.5576×10^{-4} and $1 - 1.5576 \times 10^{-4}$, respectively.

In general, the molar ratio of a doubly substituted isotopologue, which contains two heavy isotope atoms in one molecule, increases with decreasing temperature.

Let us consider the molar ratio of CO_2 molecules with molecular weights of 44 and 47, which are described as $CO_2[44]$ and $CO_2[47]$ below. The quantity Δ_{47} is defined as:

$$\Delta_{47} = \frac{R_{47}}{R_{47}^*} - 1 \tag{10}$$

 R_{47} refers to $\frac{[CO_2[47]]}{[CO_2[44]]}$ in the sample and R_{47}^* to $\frac{[CO_2[47]]}{[CO_2[44]]}$ at $T \to +\infty$. The natural abundances of carbon and oxygen atoms are shown below; ignore isotopes that are not shown here.

	¹² C	¹³ C
natural abundance	0.988888	0.011112

	¹⁶ O	¹⁷ O	¹⁸ O
natural abundance	0.997621	0.0003790	0.0020000

The temperature dependence of Δ_{47} is determined as follows, where T is given as the absolute temperature in units of K:

$$\Delta_{47} = \frac{36.2}{T^2} + 2.920 \times 10^{-4} \tag{11}$$

A.4 The R_{47} of fossil plankton obtained from the Antarctic seabed was 4.50865×10^{-5} . 9pt **Estimate** the temperature using this R_{47} . This temperature is interpreted as the air temperature during the era in which the plankton lived. Consider only the most common isotopologue of $CO_2[47]$ for the calculation.

Lambert-Beer Law?

	8 % of the total					
Question A.1 B.1 B.2 Total						
Points 10 6 6 22						
Score						

In this problem, ignore the absorption of the cell and the solvent. The temperatures of all solutions and gases are kept constant at 25 °C.

Part A

An aqueous solution **X** was prepared using HA and NaA.

The concentrations [A⁻], [HA], and [H⁺] in solution **X** are 1.00×10^{-2} mol L⁻¹, 1.00×10^{-3} mol L⁻¹, and 1.00×10^{-4} mol L⁻¹, respectively, which are correlated via the following acid-base equilibrium:

$$\mathsf{HA} \rightleftharpoons \mathsf{A}^- + \mathsf{H}^+ \qquad \qquad K = \frac{[\mathsf{A}^-][\mathsf{H}^+]}{[\mathsf{HA}]} \tag{1}$$

The optical path length is *l* in Part A. Ignore the density change upon dilution. Assume that no chemical reactions other than eq 1 occur.

A.1	The absorbance of X was A_1 at a wavelength of λ_1 .	10pt
	Then, solution X was diluted to twice its initial volume using hydrochloric acid	-
	with pH = 2.500. After the dilution, the absorbance was still A_1 at λ_1 .	
	Determine the ratio $\varepsilon_{HA}/\varepsilon_{A^{-}}$, where ε_{HA} and $\varepsilon_{A^{-}}$ represent the absorption coef-	
	ficients of HA and of A ⁻ , respectively, at λ_1 .	

Part B

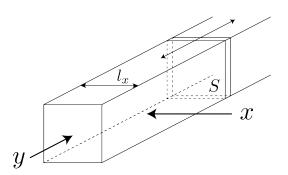

Let us consider the following equilibrium in the gas phase.

$$D \rightleftharpoons 2M$$
 (2)

Pure gas D is filled into a cuboid container that has a transparent movable wall with a cross-section of S (see the figure below) at a pressure P, and equilibrium is established while the total pressure is kept at P.

The absorbance of the gas is $A = \varepsilon(n/V)l$, where ε , n, V, and l are the absorption coefficient, amount of the gas in moles, volume of the gas, and optical path length, respectively.

Assume that all components of the gas mixture behave as ideal gases.

Use the following definitions if necessary.

	Initial state		After equilibrium		
	D	М	D	М	
Partial pressure	Р	0	p_{D}	p_{M}	
Amount in moles	n_0	0	n_{D}	n_{M}	
Volume	V ₀		V		

B.1 The absorbance of the gas at λ_{B1} measured from direction x ($l = l_x$) was A_{B1} 6pt both at the initial state and after the equilibrium. <u>Determine</u> the ratio $\varepsilon_D / \varepsilon_M$ at λ_{B1} , where ε_D and ε_M represent the absorption coefficients of D and of M, respectively.

B.2 The absorbance of the gas at λ_{B2} measured from direction y was A_{B2} both at 6pt the initial state ($l = l_{y0}$) and after the equilibrium ($l = l_y$). **Determine** the ratio $\varepsilon_D / \varepsilon_M$ at λ_{B2} .

The Redox Chemistry of Zinc

11 % of the total								
Question	A.1	A.2	B.1	B.2	B.3	B.4	Total	
Points	6	5	4	3	5	9	32	
Score								

Zinc has long been used as alloys for brass and steel materials. The zinc contained in industrial wastewater is separated by precipitation to detoxify the water, and the precipitate is reduced to re-use it as metallic zinc.

Part A

The dissolution equilibrium of zinc hydroxide $Zn(OH)_2(s)$ at 25 °C and the relevant equilibrium constants are given in eq. 1–4.

$$\operatorname{Zn}(\operatorname{OH})_2(\mathbf{s}) \rightleftharpoons \operatorname{Zn}^{2+}(\operatorname{aq}) + 2\operatorname{OH}^-(\operatorname{aq}) \qquad K_{\operatorname{sp}} = 1.74 \times 10^{-17}$$
 (1)

$$\operatorname{Zn}(\operatorname{OH})_2(s) \rightleftharpoons \operatorname{Zn}(\operatorname{OH})_2(\operatorname{aq})$$
 $K_1 = 2.62 \times 10^{-6}$ (2)

$$\operatorname{Zn}(\operatorname{OH})_2(\mathsf{s}) + 2\operatorname{OH}^-(\mathsf{aq}) \rightleftharpoons \operatorname{Zn}(\operatorname{OH})_4^{2-}(\mathsf{aq}) \qquad \qquad K_2 = 6.47 \times 10^{-2} \tag{3}$$

$$H_2O(I) \rightleftharpoons H^+(aq) + OH^-(aq) \qquad K_w = 1.00 \times 10^{-14}$$
(4)

The solubility, *S*, of zinc (total concentration of zinc in a saturated aqueous solution) is given in eq. 5.

$$S = [Zn^{2+}(aq)] + [Zn(OH)_2(aq)] + [Zn(OH)_4^{2-}(aq)]$$
(5)

- **A.1** When the equilibria in eq. 1–4 are established, <u>calculate</u> the pH range 6pt in which $[Zn(OH)_2(aq)]$ is the greatest among $[Zn^{2+}(aq)]$, $[Zn(OH)_2(aq)]$ and $[Zn(OH)_4^{2-}(aq)]$.
- A.2 A saturated aqueous solution of Zn(OH)₂(s) with pH = 7.00 was prepared and 5pt filtered. NaOH was added to this filtrate to increase its pH to 12.00.
 <u>Calculate</u> the molar percentage of zinc that precipitates when increasing the pH from 7.00 to 12.00. Ignore any volume or temperature changes.

Part B

Next, the recovered zinc hydroxide is heated to obtain zinc oxide according to the reaction below:

$$Zn(OH)_2(s) \rightarrow ZnO(s) + H_2O(I)$$
(6)

The zinc oxide is then reduced to metallic zinc by reaction with hydrogen:

$$ZnO(s) + H_2(g) \rightarrow Zn(s) + H_2O(g)$$
(7)

B.1 In order for reaction (7) to proceed at a hydrogen pressure kept at 1 bar, it is 14pt necessary to reduce the partial pressure of the generated water vapor. <u>**Calculate**</u> the upper limit for the partial pressure of water vapor to allow reaction (7) to proceed at 300 °C. Here, the Gibbs formation energies of zinc oxide and water vapor at 300 °C and 1 bar for all gaseous species are $\Delta G_{ZnO}(300^{\circ}C) = -2.90 \times 10^{2} \text{ kJ mol}^{-1}$ and $\Delta G_{H_2O}(300^{\circ}C) = -2.20 \times 10^{2} \text{ kJ mol}^{-1}$, respectively.

Metallic zinc is used as a negative electrode (anode) material for metal-air batteries. The electrode consists of Zn and ZnO. It uses the following redox reaction to generate electricity with the electromotive force (e.m.f.) at 25 °C and pressure of 1 bar, E° .

$$\operatorname{Zn}(s) + \frac{1}{2}O_2(g) \rightarrow \operatorname{ZnO}(s)$$
 $E^\circ = 1.65 \,\mathrm{V}$ (8)

B.2A zinc-air battery was discharged at 20 mA for 24 hours.3ptCalculatethe change in mass of the negative electrode (anode) of the battery.

NZL-1 C-4 Q-3

Mt. Fuji

B.3	Consider the change of e.m.f. of a zinc–air battery depending on the environment. <u>Calculate</u> the e.m.f. of a zinc–air battery at the summit of Mt. Fuji, where the temperature and altitude are -38 °C (February) and 3776 m, respectively. The pressure of the atmosphere at a given altitude is represented by						
	$P\left[bar\right] = 1.013 \times \left(1 - \frac{0.0065h}{T + 0.0065h + 273.15}\right)^{5.257} \tag{9}$						
	at altitude h [m] and temperature T [°C]. The molar ratio of oxygen in the atmosphere is 21%. The Gibbs energy change of reaction (8) is $\Delta G_{ZnO}(-38^{\circ}C) = -3.26 \times 10^{2} \text{ kJ mol}^{-1}$ at $-38^{\circ}C$ and 1 bar.						
B.4	<u>Calculate</u> the Gibbs energy change for reaction (6) at $25 ^{\circ}$ C. Note that the standard reduction potentials, $E^{\circ}(Zn^{2+}/Zn)$ and $E^{\circ}(O_2/H_2O)$ at $25 ^{\circ}$ C and 1 bar are given in (10) and (11), respectively.						
	$Zn^{2+} + 2e^- \rightarrow Zn$ $E^{\circ}(Zn^{2+}/Zn) = -0.77 V$ (10)						
	$O_2 + 4H^+ + 4e^- \rightarrow 2H_2O$ $E^{\circ}(O_2/H_2O) = 1.23V$ (11)

Although silicon is also a group 14 element like carbon, their properties differ significantly.

Part A

Unlike the carbon–carbon triple bond, the silicon–silicon triple bond in a compound formulated as R^1 –Si \equiv Si– R^1 (R: organic substituent) is extremely reactive.

For example, it reacts with ethylene to form a cyclic product that contains a four-membered ring.

When $R^1-Si \equiv Si-R^1$ is treated with an alkyne ($R^2-C \equiv C-R^2$), the four-membered-ring compound **A** is formed as an initial intermediate.

Further reaction of another molecule of $R^2-C \equiv C-R^2$ with **A** affords isomers **B** and **C**, both of which have benzene-like cyclic conjugated structures, so-called 'disilabenzenes' that contain a six-membered ring

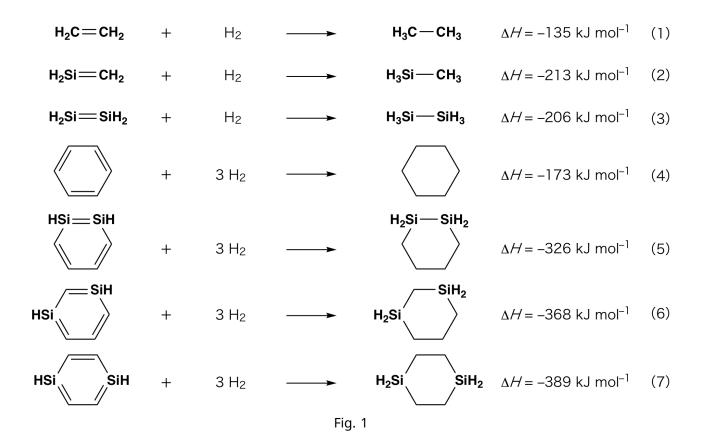

and can be formulated as $(R^1-Si)_2(R^2-C)_4$.

$$R^1-Si\equiv Si-R^1 + R^2-C\equiv C-R^2 \longrightarrow A \xrightarrow{R^2-C\equiv C-R^2} B + C$$

The ¹³C NMR analysis of the corresponding six-membered ring skeletons Si_2C_4 shows two signals for **B** and one signal for **C**.

- **A.1 Draw** the structural formulae of **A**, **B**, and **C** using R¹, R², Si, and C, with one of 9pt the possible resonance structures.
- **A.2** Calculate the aromatic stabilization energy (ASE) for benzene and **C** (in the case 7pt of $R^1 = R^2 = H$) as positive values, considering the enthalpy change in some hydrogenation reactions of unsaturated systems shown below (Fig. 1).

When a xylene solution of **C** is heated, it completely undergoes isomerisation to give a mixture of compounds **D** and **E** in equilibrium.

The molar ratio is **D** : **E** = 1 : 40.0 at 50.0 °C and **D** : **E** = 1 : 20.0 at 120.0 °C.

Calculate ΔH for the transformation of **D** to **E**. Assume that ΔH does not de-A.3 6pt pend on temperature.

The isomerization from **C** to **D** and to **E** proceeds via transformations of π -bonds into σ -bonds without breaking any σ -bonds.

A ¹³C NMR analysis revealed one signal for the Si_2C_4 skeleton of **D** and two signals for that of **E**.

The skeleton of **D** does not contain any three-membered rings, while **E** has two three-membered rings that share an edge.

A.4 Draw the structural formulae of D and E using R ¹ , R ² , Si, and C. 10pt	A.4	Draw the structural formulae of D and E using R ¹ , R ² , Si, and C.	10pt
--	-----	---	------

Part B

Silicon is able to form highly coordinated compounds (> four substituents) with electronegative elements such as fluorine. As metal fluorides are often used as fluorination reagents, highly coordinated silicon fluorides also act as fluorination reagents.

The fluorination reaction of CCl_4 using Na_2SiF_6 was carried out as follows.

• Standardization of Na₂SiF₆ solution :

Preparation

Aqueous solution **F**: 0.855 g of Na₂SiF₆ (188.053 g mol⁻¹) dissolved in water (total volume: 200 mL).

Aqueous solution **G**: 6.86 g of $Ce_2(SO_4)_3$ (568.424 g mol⁻¹) dissolved in water (total volume: 200 mL).

Procedure

Precipitation titration of a solution **F** (50.0 mL) by dropwise adding solution **G** in the presence of xylenol orange, which coordinates to Ce^{3+} , as an indicator.

After adding 18.8 mL of solution **G**, the colour of the solution changes from yellow to magenta.

The precipitate formed is a binary compound that contains Ce³⁺, and the only resulting silicon compound is Si(OH)₄.

B.1 Write the balanced equation for the reaction of Na_2SiF_6 with $Ce_2(SO_4)_3$.

5pt

• Reaction of CCl₄with Na₂SiF₆:

(Material losses by e.g., evaporation, are negligible during the following operations.)

 $Na_2SiF_6(x [g])$ was added to CCl_4 (500.0 g) and heated to 300°C in a sealed pressure-resistant reaction vessel.

The unreacted Na₂SiF₆ and generated NaCl were removed by filtration. The filtrate was diluted to a total volume of 1.00 L with CCl_4 (solution **H**).

The ²⁹Si and ¹⁹F NMR spectra of solution **H** showed SiF₄ as the only silicon compound.

In the ¹⁹F NMR spectrum, in addition to SiF₄, signals corresponding to CFCl₃, CF₂Cl₂, CF₃Cl, and CF₄ were observed (*see* Table 1). The integration ratios in the ¹⁹F NMR spectrum are proportional to the number of fluorine nuclei.

	Та	ble 1		
¹⁹ F NMR data	CFCl ₃	CF ₂ Cl ₂	CF ₃ Cl	CF ₄
Integration ratio	45.0	65.0	18.0	2.0

 SiF_4 is hydrolyzed to form H_2SiF_6 according to the following eq. 8:

$$3SiF_4 + 2H_2O \rightarrow SiO_2 + 2H_2SiF_6 \tag{8}$$

Solution **H** (10 mL) was added to an excess amount of water, which resulted in the complete hydrolysis of SiF_4 .

After separation, the H_2SiF_6 generated from the hydrolysis in the aqueous solution was neutralized and completely converted to Na_2SiF_6 (aqueous solution **J**).

The precipitate of unreacted Na_2SiF_6 and NaCl, which was removed by filtration in the initial step (underlined), was completely dissolved in water to give an aqueous solution (solution **K**; 10.0 L).

Then, additional precipitation titrations using solution **G** were carried out, and the endpoints of the titrations with **G** were as follows:

•For solution **J** (entire amount): 61.6 mL.

•For 100 mL of solution **K**: 44.4 mL.

Note: the presence of NaCl or SiO_2 has no effect on the precipitation titration.

- **B.2** Calculate the mass of the NaCl produced in the reaction vessel (information 15pt underlined), and calculate the mass (x [g]) of the Na₂SiF₆ used as a starting material.
- **B.3** 77.8% of the CCl_4 used as a starting material was unreacted. <u>Calculate</u> the mass 8pt of CF_3Cl generated.

Volcano at Sakurajima island

Part A

Japan has a very large number of volcanos. When silicate minerals crystallize from magma, some transition-metal ions (M^{n+}) in the magma are incorporated into the silicate minerals.

The M^{n+} in this problem are coordinated by oxide ions (O^{2-}) and adopt a four-coordinate tetrahedral (T_d) geometry in the magma and six-coordinate octahedral (O_h) geometry in the silicate minerals, both of which exhibit a high-spin electron configuration.

The distribution coefficient of Mⁿ⁺ between the silicate minerals and magma, *D*, can be expressed as:

$$D = \frac{[M]_s}{[M]_l}$$

 $[M]_s$ and $[M]_l$ are the concentrations of M^{n+} in the silicate minerals and the magma, respectively. The table below gives D for Cr^{2+} and Mn^{2+} examples.

 Δ_{O} and CFSE^O represent the energy separation of the d-orbitals of Mⁿ⁺ and the crystal-field stabilization energy in a O_{h} field, respectively. Δ_{T} and CFSE^T are these in a T_{d} field.

- **A.1** <u>**Calculate**</u> $|CFSE^O CFSE^T| = \Delta CFSE$ in terms of Δ_O for Cr^{2+} , Mn^{2+} , and Co^{2+} ; 6pt assume $\Delta_T = 4/9\Delta_O$.
- A linear relationship is observed when $\ln D$ is plotted against $\Delta CFSE / \Delta_0$ in the A.2 3pt Cartesian coordinate system shown below. **<u>Estimate</u>** D for Co²⁺. 2.0 1.5 Q <u>L</u> 1.0 0.5 0 0.2 0.3 0 0.1 0.4 0.5 $\Delta CFSE / \Delta_0$

Metal oxides MO (M: Ca, Ti, V, Mn, or Co) crystallize in a rock-salt structure wherein the M^{n+} adopts an O_h geometry with a high-spin electron configuration.

The lattice enthalpy of these oxides is mainly governed by the Coulomb interactions based on the radius and charge of the ions and some contributions from the CFSE of M^{n+} in the O_h field.

<u>Choose</u> the appropriate set of lattice enthalpies [k] mol⁻¹] from one of the op-A.3 3pt tions (a) to (f). VO CaO TiO MnO CoO 3460 3878 3913 3810 (a) 3916 (b) 3460 3916 3878 3810 3913 3460 3913 3916 3810 3878 (C) (d) 3810 3878 3913 3460 3916 3810 3916 3878 3460 3913 (e) 3810 3913 3916 3460 3878 (f)

Part B

A mixed oxide **A**, which contains La^{3+} and Cu^{2+} , crystallizes in a tetragonal unit cell shown in Fig.1.

In the $[CuO_6]$ octahedron, the Cu–O length along the *z*-axis (l_z) is longer than that of the *x*-axis (l_x), and $[CuO_6]$ is distorted from the regular O_h geometry.

This distortion removes the degeneracy of the e_q orbitals ($d_{x^2-y^2}$ and d_{z^2}).

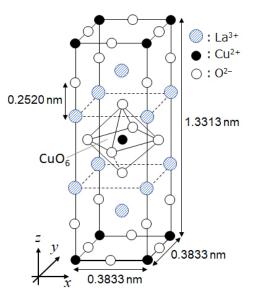

Fig. 1

A can be synthesized by thermal decomposition (pyrolysis) of complex **B**, which is formed by mixing metal chlorides in dilute aqueous ammonia solution containing squaric acid $C_4H_2O_4$ (a diacid).

Pyrolysis **B** in dry air results in a weight loss of 29.1% up to 200 °C due to the loss of waters of crystallization. This is followed by release of CO_2 at temperatures up to 700 °C.

The total weight loss during the formation of **A** from **B** is 63.6%. It should be noted that only water and CO_2 are released in the pyrolysis reaction.

B.1	Write the chemical formulae for A and B .	6pt
B.2	<u>Calculate</u> l_x and l_z using Fig. 1.	4pt
B.3	For Cu^{2+} in the distorted $[CuO_6]$ octahedron in A of Fig. 1: <u>write</u> the names of the split e _g orbitals (d _{x²-y²} and d _{z²}) in (i) and (ii). <u>draw</u> the electron configuration in the dotted box on your answer sheet.	4pt

A is an insulator. When one La^{3+} is substituted with one Sr^{2+} , one hole is generated in the crystal lattice that can conduct electricity. As a result, the Sr^{2+} -doped **A** shows superconductivity below 38 K.

When a substitution reaction took place in $\bm{A}, 2.05\times 10^{27}$ holes m^{-3} were generated.

B.4 <u>**Calculate**</u> the percentage of Sr²⁺ substituted for La³⁺ based on the mole ratio 4pt in the substitution reaction. Note that the valences of the constituent ions and the crystal structure are not altered by the substitution reaction.

Part C

 $Cu_2(CH_3CO_2)_4$ is composed of four $CH_3CO_2^-$ coordinated to two Cu^{2+} (Fig. 2A). $Cu_2(CH_3CO_2)_4$ exhibits high levels of structural symmetry. Two axes pass through the carbon atoms of the four $CH_3CO_2^-$ and an axis passes through the two Cu^{2+} . All of these are oriented orthogonal relative to each other.

When a dicarboxylate ligand is used instead of $CH_3CO_2^-$, a "cage complex" is formed. The cage complex $Cu_4(L1)_4$ is composed of planar dicarboxylate **L1** (Fig. 2B) and Cu^{2+} (Fig. 2C).

The angle θ between the coordination directions of the two carboxylates, indicated by the arrows in Fig. 2B, determines the structure of the cage complex. The θ is 0° for **L1**. Note that hydrogen atoms are not shown in Fig. 2.

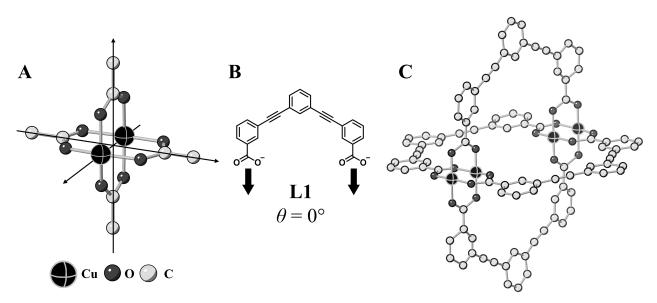

Fig. 2

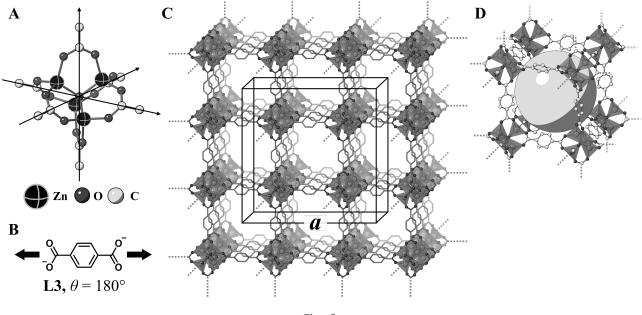

A zinc complex, $Zn_4O(CH_3CO_2)_6$, contains four tetrahedral Zn^{2+} , six $CH_3CO_2^{--}$, and one O^{2-} (Fig. 3A). In $Zn_4O(CH_3CO_2)_6$.

The O^{2-} is located at the origin, and the three axes passing through the carbon atoms of $CH_3CO_2^-$ are oriented orthogonal relative to each other.

When *p*-benzenedicarboxylate (Fig. 3B, **L3**, θ = 180°) is used instead of CH₃CO₂⁻, the Zn²⁺ clusters are linked to each other to form a crystalline solid (**X**) that is called a "porous coordination polymer" (Fig. 3C).

The composition of **X** is $[Zn_4O(L3)_3]_n$, and it has a cubic crystal structure with nano-sized pores. One pore is represented as a sphere in Fig. 3D.

Each tetrahedral Zn²⁺ cluster is represented as dark grey polyhedron in Fig. 3C and 3D. Hydrogen atoms are not shown in Fig. 3.

- **C.2 X** has a cubic unit cell with a side length of *a* (Fig. 3C) and a density of 0.592 5pt $g \text{ cm}^{-3}$. **Calculate** *a* in [cm].
- **C.3** X contains a considerable number of pores. 1 g of X can accommodate 3.0×10^2 5pt mL of CO₂ gas in the pores at 1 bar and 25 °C. **Calculate** the average number of CO₂ molecules per pore.

Part A

Inula linariifolia

NZL-1 C-7 Q-2

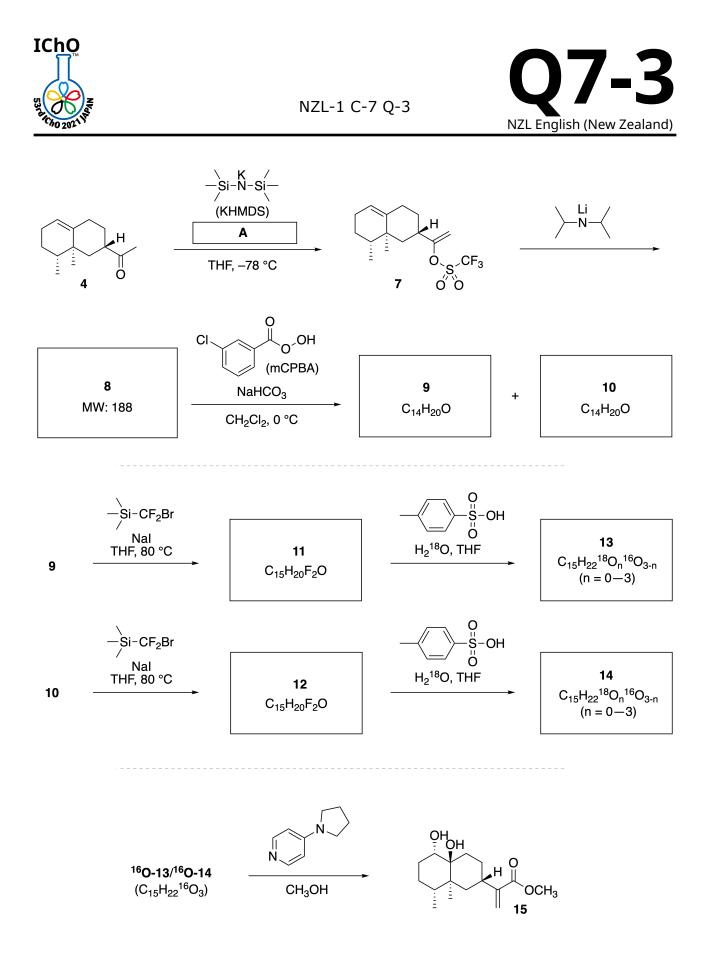

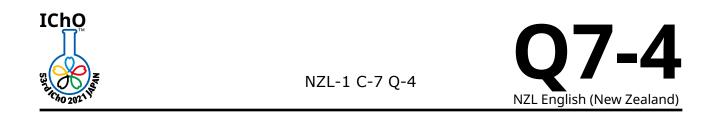

A.1 The natural product lineariifolianone, was isolated from *Inula linariifolia*. Valencene (1) can be converted in a one-step process to 2. 2 is converted in three-step process via 3 to ketone 4. Eremophilene (5) is converted into 6 using the same four-step process.
 Draw structures of 2 and 6 clearly show stereochemistry where necessary.

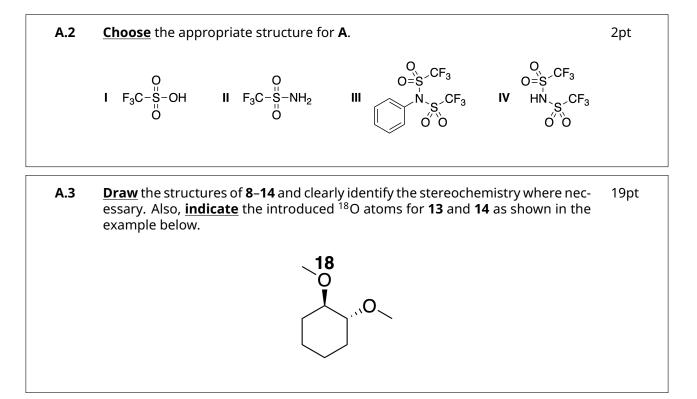

Then, ketone **4** is converted by a multi-step process into ester **15**.

Compound **8** (molecular weight: 188) retains all stereocenters in **7**. Compounds **9** and **10** have five stereocenters and no carbon-carbon double bonds.

Assume that $H_2^{18}O$ is used instead of $H_2^{16}O$ for the synthesis of ¹⁸O-labelled-lineariifolianones **13** and **14** from **11** and **12**, respectively. Compounds **13** and **14** are ¹⁸O-labelled isotopomers. If the isotopic labelling is ignored, both **13** and **14** provide the same product **15** with identical stereochemistry.

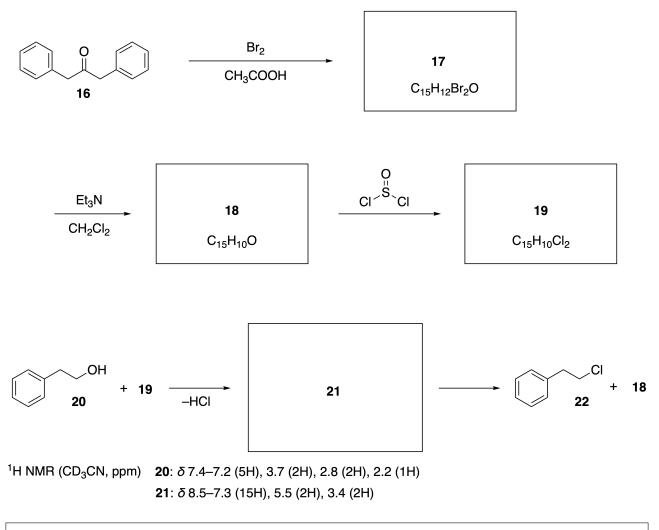

Part B

Compound **19** is synthesized as shown below. In relation to non-benzenoid aromaticity, **19** can be used as an activator for alcohols, and **20** was converted to **22** via ion-pair intermediate **21**. Although the formation of **21** was observed by NMR, **21** gradually decomposes to give **18** and **22**.

B.1 Draw the structures of **17–19** and **21**. Identifying the stereochemistry is not 10pt necessary.

Polycyclic aromatic hydrocarbons with successive ortho-connections are called [n]carbohelicenes (n represents the number of six-membered rings) (see below). [4]Carbohelicene ([4]C) is efficiently prepared, using a photoreaction of the type shown below, via an intermediate (**Int.**) that is readily oxidized by iodine.

The photoreaction proceeds in a manner similar to the following example.

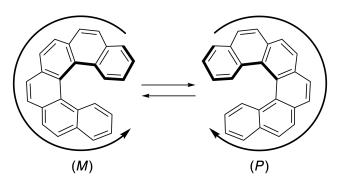

NZL-1 C-8 Q-2

Note: For all of Question 8, please draw alternating single and double bonds in your answers as shown in the examples of carbohelicene. Do not use circles for conjugated π systems.

A.1 Draw the structures of A-C. Stereoisomers should be distinguished.
 9pt
 A.2 Attempts to synthesize [5]carbohelicene from the phosphonium salt above and an appropriate starting compound resulted in the formation of only a trace amount of [5]carbohelicene. This reaction gave product D having a molecular weight 2 Da lower than [5]carbohelicene. The ¹H NMR chemical shifts of D are shown below.
 [D (δ, ppm in CS₂, r.t.), 8.85 (2H), 8.23 (2H), 8.07 (2H), 8.01 (2H), 7.97 (2H), 7.91 (2H)]
 Draw the structure of D.

[5]- and larger [n]carbohelicenes have helical chirality and interconversion between enantiomers of these helicenes is significantly slow at room temperature. The configuration of [n]carbohelicenes is defined as (*M*) or (*P*) as shown below.

[n]Carbohelicenes with n larger than 4 can be separated into enantiomers by a chiral column chromatography, which was developed by Prof. Yoshio Okamoto.

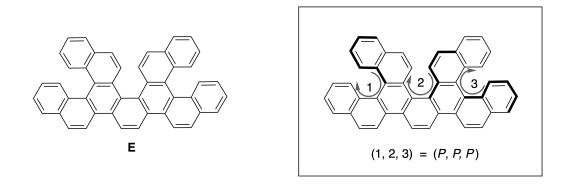

Photo courtesy: The Japan Prize Foundation

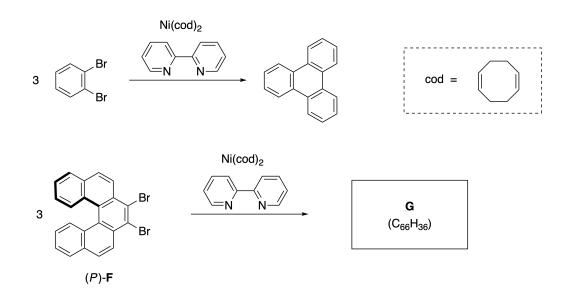

Q8-3 NZL English (New Zealand)

Multiple helicenes are molecules that contain two or more helicene-like structures. If its helical chirality is considered, several stereogenic (stereoisomeric) centres exist in a multiple helicene. For example, compound **E** contains three [5]carbohelicene-like moieties in one molecule. One of the stereoisomers is described as (P, P, P) as shown below.

A.3 The nickel-mediated trimerization of 1,2-dibromobenzene generates triphenylene as shown below. When the same reaction is applied to an enantiomer of **F**, (*P*)-**F**, multiple helicene **G** ($C_{66}H_{36}$) is obtained. Assuming that interconversion between stereoisomers does not occur during the reaction, **identify all** possible stereoisomers of **G** formed in this process, without duplication. One isomer should be drawn completely with the chirality defined as in the example, using numerical labels. Other stereoisomers should be listed with location numbers and *M* and *P* labels according to the same numbering. For instance, the other stereoisomers of **E** should be listed as (1, 2, 3) = (*P*, *M*, *P*), (*P*, *M*, *M*), (*P*, *P*, *M*), (*M*, *M*, *M*), (*M*, *M*, *P*), (*M*, *P*, *P*), and (*M*, *P*, *M*).

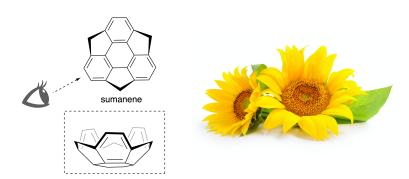

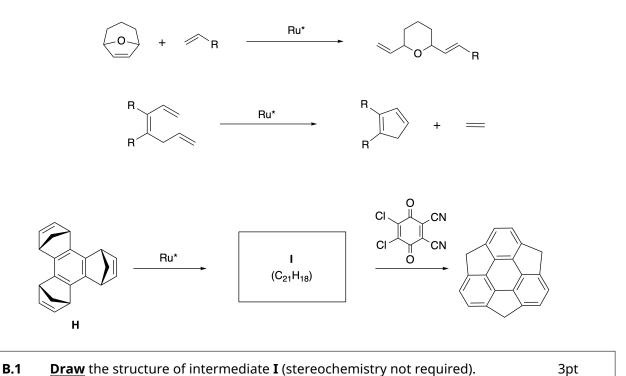

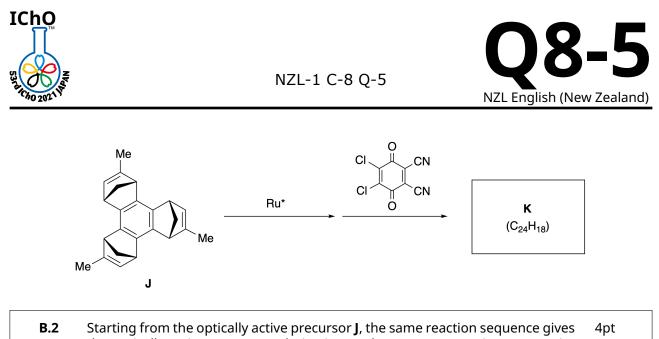

Part B

Sumanene is a bowl-shaped hydrocarbon that was first reported in Japan in 2003. The name "sumanene" derives from a Sanskrit-Hindi word "suman" that means sunflower. The synthesis of sumanene was achieved by a reaction sequence that consists of a ring-opening and a ring-closing metathesis.

Representative metathesis reactions catalyzed by a ruthenium catalyst (Ru*) are shown below.

the optically active sumanene derivative **K**. The stereocenters in **J** are not inverted during the metathesis reaction. **Draw** the structure of **K** with appropriate stereochemistry.

Good kids don't do this, but if you cut a tennis ball on the seam, you can disassemble it into two U-shaped pieces.

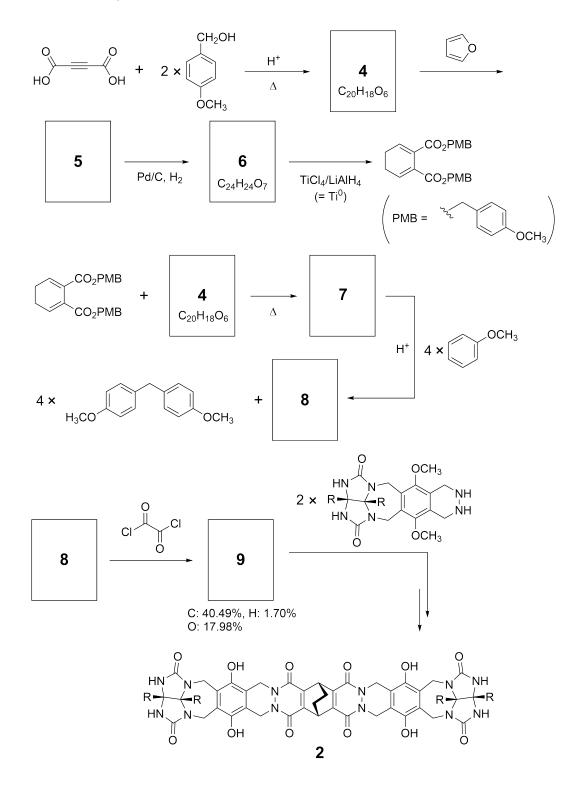

Based on this idea, compounds **1** and **2** were synthesized as U-shaped molecules of different sizes. Compound **3** was prepared as a model of **1**. The encapsulation behaviour of these was investigated.

The synthetic route to **2** is shown below. The elemental composition of compound **9** is C; 40.49%, H; 1.70%, and O; 17.98% by mass.

A.1 <u>Draw</u> the structures of **4–9**. It is not necessary to show stereochemistry. Use 13pt "PMB" as an abbreviation so that you do not need to draw the structure of *p*-methoxybenzyl group shown in the scheme above.

In the mass spectrum of **1**, an ion peak corresponding to its dimer (1_2) was clearly observed, whereas an ion peak for the dimer of **3** (3_2) was not observed in the spectrum of **3**. In the ¹H NMR spectra of a solution of 1_2 , all N-H protons derived from **1** were observed to be chemically equivalent, and their chemical shift was significantly different from that of the N-H protons of **3**. This indicates that hydrogen bonds are formed between the NH groups of **1** and atoms **X** of another molecule of **1** to form the dimeric capsule.

A.2	<u>Circle</u> all the appropriate atom(s) X in 1 .	2pt
A.3	<u>Give</u> the number of the hydrogen bonds in the dimeric capsule (1_2).	2pt

NZL-1 C-9 Q-4 NZL English (New Zealand)

The dimeric capsule of $\mathbf{1}$ ($\mathbf{1}_2$) has an internal space wherein an appropriate small molecule Z can be encapsulated. This phenomenon is expressed by the following reaction equation:

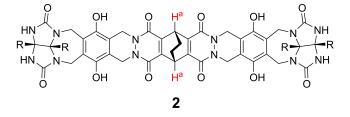

$$\mathsf{Z} + \mathbf{1}_2 \to \mathsf{Z} \textcircled{\texttt{0}} \mathbf{1}_2 \tag{1}$$

The equilibrium constant for the encapsulation of Z into $\mathbf{1}_2$ is given as below:

$$K_{\mathsf{a}} = \frac{[\mathsf{Z}@\mathbf{1}_2]}{[\mathsf{Z}][\mathbf{1}_2]} \tag{2}$$

Encapsulation of a molecule can be monitored by NMR spectroscopy. For example, 1_2 in C₆D₆ gave different signals in the ¹H NMR spectra before and after addition of CH₄.

Compound **2** also forms a rigid and larger dimeric capsule (2_2). The ¹H NMR spectrum of 2_2 was measured in C₆D₆, C₆D₅F, and a C₆D₆/C₆D₅F solvent mixture, with all other conditions being kept constant. The chemical shifts for the H^a proton of **2** in the above solvents are summarized below. No other signals from the H^a in **2**, except for those listed, were observed. Assume that the interior of the capsule is always filled with the largest possible number of solvent molecules and that each signal corresponds to one species of the filled capsule.

solvent	δ (ppm) of H ^a
C ₆ D ₆	4.60
C ₆ D ₅ F	4.71
C ₆ D ₆ / C ₆ D ₅ F	4.60, 4.71, 4.82

A.4 Determine the number of C_6D_6 and C_6D_5F molecules encapsulated in 2_2 giving 3pt each H^a signal.

 1 H NMR measurements in $\rm C_6D_6$ revealed that 2_2 can incorporate one molecule of 1-adamantanecarboxylic acid (AdA).

The association constants (K_a) which are expressed below were determined for various temperatures. [solvent@ 2_2] denotes a species containing one or more solvent molecules.

$$K_{\mathsf{a}} = \frac{[\mathsf{Z}@\mathbf{2}_2]}{[\mathsf{Z}][\mathsf{solvent}@\mathbf{2}_2]} \tag{3}$$

Similarly, K_a for association of CH₄ and 1_2 (see eq (2)), was determined at various temperatures by ¹H NMR measurements in C₆D₆. The plots of the two association constants (as ln K_a vs 1/*T*) are shown below.

No C_6D_6 molecule is encapsulated in $\mathbf{1}_2$. In line **II**, the entropy change (ΔS) is (1) and enthalpy change (ΔH) is (2), indicating that the driving force for the encapsulation in line **II** is (3). Therefore, line **I** corresponds to (4), and line **II** corresponds to (5).

	A	В	
(1)	positive	negative	
(2)	positive	negative	
(3)	ΔS	ΔH	
(4)	1_2 and CH_4	2_2 and AdA	
(5)	1_2 and CH_4	2_2 and AdA
