IChO General instructions Cover sheet

Please return this cover sheet together with all the related question sheets.

International Chemistry Olympiad 2021 Japan 53rd IChO2021 Japan 25th July – 2nd August, 2021 https://www.icho2021.org

General Instructions

- You are allowed to use pen only to write your answers.
- Your calculator must be non-programmable.
- This examination has 9 problems.
- You can solve the problems in any order.
- You will have **5 hours** to solve all problems.
- You can **begin** working only after the **START** command is given by the invigilator.
- All results must be written in the appropriate answer boxes with pen on the **answer sheets**. If you need scratch paper, use the back of the question sheets. Remember that answers written outside the answer boxes will not be graded.
- Write relevant calculations in the appropriate boxes when necessary. Work must be shown to receive full credit for correct answers.
- The invigilator will announce a **30-minute** warning before the **STOP** command.
- You **must stop** working when the **STOP** command is given. Failure to stop writing will lead to the nullification of your examination.
- The official English version of this examination is available by request for clarification only.
- You are not allowed to leave your seat without permission from the invigilator. If you need any assistance (broken calculator, need to use a restroom, etc.), raise your hand to get the attention of the invigilator.

GOOD LUCK!

Hydrogen at a Metal Surface

11 % of the total									
Question	A.1	A.2	B.1	B.2	B.3	B.4	Total		
Points	6	4	5	3	3	3	24		
Score									

Hydrogen is expected to be a future energy source that does not depend on fossil fuels. Here, we will consider the hydrogen-storage process in a metal, which is related to hydrogen-transport and hydrogen-storage technology.

Part A

As hydrogen is absorbed into the bulk of a metal surface, let us first consider the adsorption process of hydrogen at the metal surface, $H_2(g) \to 2H(ad)$, where the gaseous and adsorbed states of hydrogen are represented as (g) and (ad), respectively. Hydrogen molecules (H_2) that reach the metal surface (M) dissociate at the surface and are adsorbed as H atoms (Fig. 1). Here, the potential energy of H_2 is represented by two variables: the interatomic distance, d, and the height relative to the surface metal atom, z. It is assumed that the axis along the two H atoms is parallel to the surface and that the center of gravity is always on the vertical dotted line in Figure 1.

Figure 2 shows the potential energy contour plot for the dissociation at the surface. The numerical values represent the potential energy in units of kJ per mole of H_2 . The solid line spacing is 20 kJ mol⁻¹, the dashed line spacing is 100 kJ mol⁻¹, and the spacing between solid and dashed lines is 80 kJ mol⁻¹. The zero-point vibration energy is ignored.

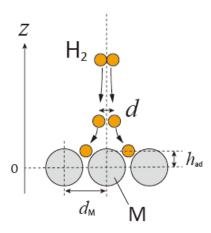

Figure 1. Definition of variables. Drawing is not to scale.

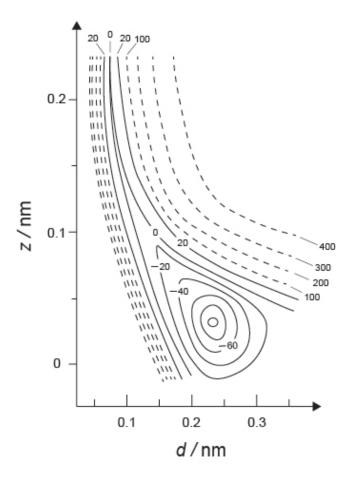

Figure 2.

- A.1 For each of the following items (i)–(iii), **SELECT** the closest value from A–G. 6pt
 - (i) The interatomic distance for a gaseous H₂ molecule
 - (ii) The interatomic distance between metal atoms (d_{M} in Figure 1)
 - (iii) The distance of adsorbed H atoms from the surface ($h_{\rm ad}$ in Figure 1)

A. 0.03 nm B. 0.07 nm C. 0.11 nm D. 0.15 nm E. 0.19 nm F. 0.23 nm G. 0.27 nm

A.2 For each of the following items (i)–(ii), **SELECT** the closest value from A–H.

4pt

- (i) the energy required for the dissociation of gaseous H $_2$ to gaseous H $[H_2(g) \to 2H(g)]$
- (ii) the energy released during the adsorption of a gaseous H_2 [$H_2(g) \rightarrow 2H(ad)$]

A. 20 kJ mol^{-1} B. 40 kJ mol^{-1} C. 60 kJ mol^{-1} D. 100 kJ mol^{-1} E. 150 kJ mol^{-1} F. 200 kJ mol^{-1} G. 300 kJ mol^{-1} H. 400 kJ mol^{-1}

Part B

The adsorbed hydrogen atoms are then either absorbed into the bulk, or recombine and desorb back into the gas phase, as shown in the reactions (1a) and (1b). H(ab) represents a hydrogen atom absorbed in the bulk.

$$H_2(g) \underset{k_2}{\overset{k_1}{\rightleftharpoons}} 2H(ad) \tag{1a}$$

$$H(ad) \xrightarrow{k_3} H(ab)$$
 (1b)

The reaction rates per surface site for adsorption, desorption, and absorption are $r_1[s^{-1}], r_2[s^{-1}]$ and $r_3[s^{-1}]$, respectively. They are expressed as:

$$r_1 = k_1 P_{\mathsf{H}_2} (1 - \theta)^2 \tag{2}$$

$$r_2 = k_2 \theta^2 \tag{3}$$

$$r_3 = k_3 \theta \tag{4}$$

where k_1 [s⁻¹ Pa⁻¹], k_2 [s⁻¹] and k_3 [s⁻¹] are the reaction rate constants and $P_{\rm H_2}$ is the pressure of $\rm H_2$. Among the sites available on the surface, θ (0 \leq θ \leq 1) is the fraction occupied by H atoms. It is assumed that adsorption and desorption are fast compared to absorption ($r_1, r_2 \gg r_3$) and that θ remains constant.

B.1 r_3 can be expressed as:

5pt

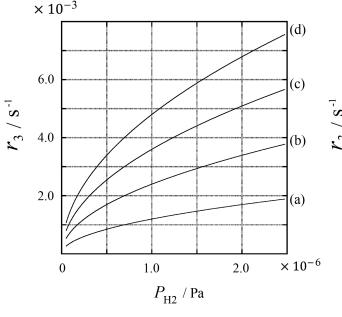

$$r_{3} = \frac{k_{3}}{1 + \sqrt{\frac{1}{P_{\text{H}_{2}}C}}} \tag{5}$$

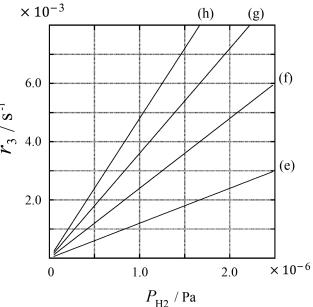

EXPRESS C using k_1 and k_2 .

A metal sample with a surface area of $S=1.0\times 10^{-3}\,\mathrm{m}^2$ was placed in a container (1L = $1.0\times 10^{-3}\,\mathrm{m}^3$) with H $_2$ ($P_{\mathrm{H}_2}=1.0\times 10^2\,\mathrm{Pa}$). The density of hydrogen-atom adsorption sites on the surface was $N=1.3\times 10^{18}\,\mathrm{m}^{-2}$. The surface temperature was kept at $T=400\,\mathrm{K}$. As the reaction (1) proceeded, P_{H_2} decreased at a constant rate of $v=4.0\times 10^{-4}\,\mathrm{Pa}$ s $^{-1}$. Assume that H $_2$ is an ideal gas and that the volume of the metal sample is negligible.

- **B.2 CALCULATE** the amount of H atoms in moles absorbed per unit area of the 3pt surface per unit time, $A \, [\text{mol s}^{-1} \, \text{m}^{-2}].$
- **B.3** At T=400 K, C equals 1.0×10^2 Pa $^{-1}$. **CALCULATE** the value of k_3 at 400 K. (If you did not obtain the answer to **B.2**, use $A=3.6\times 10^{-7}$ mol s $^{-1}$ m $^{-2}$.)
- **B.4** At a different temperature, $C=2.5\times 10^3\,{\rm Pa^{-1}}$ and $k_3=4.8\times 10^{-2}\,{\rm s^{-1}}$. For r_3 as a function of $P_{\rm H_2}$ at this temperature, **SELECT** the correct curve from (a)–(h).

Isotope Time Capsule

11 % of the total									
Question	A.1	A.2	A.3	A.4	Total				
Points	8	8	10	9	35				
Score									

Molecular entities that differ only in isotopic composition, such as CH₄ and CH₃D, are called isotopologues.

Isotopologues are considered to have the same chemical characteristics. In nature, however, there are slight differences between isotopologues.

Assume that all of the substances shown in this Question are in the gas phase.

Let us consider the following equilibrium:

$$^{12}C^{16}O_{2} + ^{12}C^{18}O_{2} \rightleftharpoons 2^{12}C^{16}O^{18}O \qquad K = \frac{[^{12}C^{16}O^{18}O]^{2}}{[^{12}C^{16}O_{2}][^{12}C^{18}O_{2}]}$$
(1)

The entropy, S, increases as the number of possible microscopic states of a system, W, increases:

$$S = k_{\mathsf{B}} \ln W \tag{2}$$

W=1 for $^{12}\mathrm{C^{16}O_2}$ and $^{12}\mathrm{C^{18}O_2}$. In contrast, W=2 for a $^{12}\mathrm{C^{16}O^{18}O}$ molecule because the oxygen atoms are distinguishable in this molecule. As the right-hand side of the equilibrium shown in equation 1 has two $^{12}\mathrm{C^{16}O^{18}O}$ molecules, $W=2^2=4$.

A.1 The enthalpy change, ΔH , of equation 3 is positive regardless of the temperature.

$$H_2 + DI \rightleftharpoons HD + HI$$
 (3)

CALCULATE the equilibrium constant, K, for equation 3 at very low temperature (think of $T\to 0$) and again at very high temperature (think of $T\to +\infty$) . Assume that the reaction remains unchanged at these temperatures and that ΔH converges to a constant value for high temperature.

 ΔH of the following process can be explained by molecular vibrations.

$$2HD \rightleftharpoons H_2 + D_2$$
 $K = \frac{[H_2][D_2]}{[HD]^2}$ (4)

At T = 0 K, the vibrational energy of a diatomic molecule whose vibration frequency is ν [s⁻¹] is expressed as:

$$E = \frac{1}{2}h\nu\tag{5}$$

$$\nu = \frac{1}{2\pi} \sqrt{\frac{k}{\mu}} \tag{6}$$

In equation 6 , k is the force constant and μ is the reduced mass.

Reduced mass is expressed in terms of the mass of the two atoms in the diatomic molecule, m_1 and m_2 , according to:

$$\mu = \frac{m_1 m_2}{m_1 + m_2} \tag{7}$$

A.2 The wavenumber corresponding to the vibration of H_2 is 4161.0 cm⁻¹. **CALCU-** 8pt **LATE** ΔH of the following equation at T = 0 K in units of J mol⁻¹.

$$2HD \rightarrow H_2 + D_2 \tag{8}$$

Assume that:

- only the vibrational energy contributes to ΔH .
- the k values for H₂, HD, and D₂ are identical.
- the mass of H is 1 Da and the mass of D is 2 Da.

The molar ratio of H_2 , HD, and D_2 depends on the temperature in a system in equilibrium. Here, Δ_{D_2} is defined as the change of the molar ratio of D_2 .

$$\Delta_{\mathsf{D}_2} = \frac{R_{\mathsf{D}_2}}{R_{\mathsf{D}_2}^*} - 1 \tag{9}$$

Here, R_{D_2} refers to $\frac{[\mathsf{D}_2]}{[\mathsf{H}_2]}$ in the sample and $R_{\mathsf{D}_2}^*$ to $\frac{[\mathsf{D}_2]}{[\mathsf{H}_2]}$ at $T \to +\infty$. Note that the distribution of isotopes becomes random at $T \to +\infty$.

A.3 CALCULATE Δ_{D_2} with natural D abundance when the isotopic exchange is in equilibrium at the temperature where K (in equation 4) is 0.300. Assume that the natural abundance ratios of D and H are 1.5576×10^{-4} and $(1-1.5576 \times 10^{-4})$, respectively.

In general, the molar ratio of the doubly substituted isotopologue, which contains two heavy isotope atoms in one molecule, increases with decreasing temperature. Let us consider the molar ratio of CO_2 molecules with molecular weights of 44 and 47, which are described as $CO_2[44]$ and $CO_2[47]$ below. The quantity Δ_{47} is defined as:

$$\Delta_{47} = \frac{R_{47}}{R_{47}^*} - 1 \tag{10}$$

 R_{47} refers to $\frac{[\mathrm{CO_2}[47]]}{[\mathrm{CO_2}[44]]}$ in the sample and R_{47}^* to $\frac{[\mathrm{CO_2}[47]]}{[\mathrm{CO_2}[44]]}$ at $T \to +\infty$. The natural abundances of carbon and oxygen atoms are shown below; ignore isotopes that are not shown here.

	¹² C	¹³ C
natural abundance	0.988888	0.011112

	¹⁶ O	¹⁷ O	¹⁸ O
natural abundance	0.997621	0.0003790	0.0020000

The temperature dependence of Δ_{47} is determined as follows, where T is given as the absolute temperature in units of K:

$$\Delta_{47} = \frac{36.2}{T^2} + 2.920 \times 10^{-4} \tag{11}$$

A.4 The R_{47} of fossil plankton obtained from the Antarctic seabed was 4.50865×10^{-5} . 9pt **CALCULATE** the approximate temperature using this R_{47} . This temperature is interpreted as the air temperature during the era in which the plankton lived. Consider only the most common isotopologue of $\text{CO}_2[47]$ for the calculation.

Lambert-Beer Law?

8 % of the total					
Question	A.1	B.1	B.2	Total	
Points	10	6	6	22	
Score					

In this problem, ignore the absorption of the cell and the solvent. The temperatures of all solutions and gases are kept constant at 25 °C.

Part A

An aqueous solution **X** was prepared using HA and NaA. The concentrations [A⁻], [HA], and [H⁺] in solution **X** are 1.00×10^{-2} mol L⁻¹, 1.00×10^{-3} mol L⁻¹, and 1.00×10^{-4} mol L⁻¹, respectively, which are correlated via the following acid-base equilibrium:

$$\mathsf{HA} \rightleftharpoons \mathsf{A}^- + \mathsf{H}^+ \qquad \qquad K = \frac{[\mathsf{A}^-][\mathsf{H}^+]}{[\mathsf{HA}]}$$
 (1)

For part A, the optical path length is $\it l$. Ignore the density change upon dilution. Assume that no chemical reactions other than equation 1 occur.

A.1 The absorbance of **X** was A_1 at a wavelength of λ_1 . Then, solution **X** was diluted to twice its initial volume using hydrochloric acid with pH = 2.500. After dilution, the absorbance was still A_1 at λ_1 . **DETERMINE** the ratio $\varepsilon_{\text{HA}}/\varepsilon_{\text{A}^-}$, where ε_{HA} and ε_{A^-} represent the absorption coefficients of HA and of A $^-$, respectively, at λ_1 .

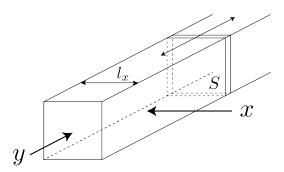

Q3-2
USA (United States of America)

Part B

Let us consider the following equilibrium in the gas phase.

$$D \rightleftharpoons 2M$$
 (2)

Pure gas D is filled into a cuboid container that has a transparent movable wall with a cross-section of S (see the figure below) at a pressure P. Equilibrium is established while the total pressure is kept at P. The absorbance of the gas is $A=\varepsilon(n/V)l$, where ε is the absorption coefficient, n is the amount of gas in moles, V is the volume of gas, and l is the optical path length. Assume that all components of the gas mixture behave as ideal gases.

Use the following definitions if necessary.

	Initial state		After equilibrium	
	D	М	D	М
Partial pressure	$P = \begin{bmatrix} 0 & 1 \end{bmatrix}$		p_{D}	p_{M}
Amount in moles	n_0 0		n_{D} n_{M}	
Volume	V_0		V	

- **B.1** The absorbance of the gas at λ_{B1} measured from direction x was A_{B1} both at the initial state ($l=l_{x0}$) and after the equilibrium ($l=l_{x}$). **DETERMINE** the ratio $\varepsilon_{\text{D}}/\varepsilon_{\text{M}}$ at λ_{B1} , where ε_{D} and ε_{M} represent the absorption coefficients of D and M, respectively.
- **B.2** The absorbance of the gas at $\lambda_{\rm B2}$ measured from direction y was $A_{\rm B2}$ both at the initial state ($l=l_{y0}$) and after the equilibrium ($l=l_{y}$). **DETERMINE** the ratio $\varepsilon_{\rm D}/\varepsilon_{\rm M}$ at $\lambda_{\rm B2}$.

The Redox Chemistry of Zinc

11 % of the total							
Question	A.1	A.2	B.1	B.2	B.3	B.4	Total
Points	6	5	4	3	5	9	32
Score							

Zinc has long been used in alloys for brass and steel materials. The zinc contained in industrial wastewater is removed by precipitation to detoxify the water, and the precipitate obtained is reduced to recover and reuse it as metallic zinc.

Part A

The dissolution equilibrium of zinc hydroxide $Zn(OH)_2(s)$ at 25 °C and the relevant equilibrium constants are given in equations 1–4.

$$\mbox{Zn(OH)}_{2}(\mbox{s}) \rightleftharpoons \mbox{Zn}^{2+}(\mbox{aq}) + 2\mbox{OH}^{-}(\mbox{aq}) \hspace{1cm} K_{\mbox{sp}} = 1.74 \times 10^{-17} \hspace{1cm} \mbox{(1)}$$

$${\rm Zn}({\rm OH})_2({\rm s})\rightleftharpoons {\rm Zn}({\rm OH})_2({\rm aq}) \hspace{1cm} K_1=2.62\times 10^{-6} \hspace{1cm} \rm (2)$$

$$\mathrm{Zn}(\mathrm{OH})_2(\mathrm{s}) + 2\mathrm{OH^-}(\mathrm{aq}) \rightleftharpoons \mathrm{Zn}(\mathrm{OH})_4^{2-}(\mathrm{aq}) \hspace{1cm} K_2 = 6.47 \times 10^{-2} \hspace{1cm} \mathrm{(3)}$$

$$H_2O(I) \rightleftharpoons H^+(aq) + OH^-(aq)$$
 $K_w = 1.00 \times 10^{-14}$ (4)

The solubility of zinc, S, (concentration of zinc in a saturated aqueous solution) is given in equation 5.

$$S = [Zn^{2+}(aq)] + [Zn(OH)_2(aq)] + [Zn(OH)_4^{2-}(aq)]$$
(5)

- **A.1** When the equilibria in equations 1–4 are established, **CALCULATE** the pH range in which $[Zn(OH)_2(aq)]$ is the greatest among $[Zn^{2+}(aq)]$, $[Zn(OH)_2(aq)]$ and $[Zn(OH)_4^{2-}(aq)]$.
- A.2 A saturated aqueous solution of $Zn(OH)_2(s)$ with pH = 7.00 was prepared and filtered. NaOH was added to this filtrate to increase its pH to 12.00. **CALCULATE** the mole percent of zinc that precipitates when increasing the pH from 7.00 to 12.00. Ignore the volume and temperature changes.

Part B

Next, the recovered zinc hydroxide is heated to obtain zinc oxide according to the reaction below:

$$Zn(OH)_2(s) \rightarrow ZnO(s) + H_2O(I)$$
 (6)

The zinc oxide is then reduced to metallic zinc by reaction with hydrogen:

$$ZnO(s) + H2(g) \rightarrow Zn(s) + H2O(g)$$
(7)

B.1 In order for reaction (7) to proceed at a constant hydrogen pressure of 1 bar, it is necessary to reduce the partial pressure of the generated water vapor. **CALCULATE** the upper limit for the partial pressure of water vapor to allow reaction (7) to proceed at 300 °C. The Gibbs formation energies of zinc oxide and water vapor at 300 °C and 1 bar for all gaseous species are $\Delta G_{\rm ZnO}(300^{\circ}{\rm C}) = -2.90 \times 10^2$ kJ mol $^{-1}$ and $\Delta G_{\rm H_2O}(300^{\circ}{\rm C}) = -2.20 \times 10^2$ kJ mol $^{-1}$, respectively.

Metallic zinc is used as a negative electrode (anode) material for metal-air batteries. The electrode consists of Zn and ZnO. It uses the following redox reaction to generate electricity with the electromotive force (e.m.f.) at 25 $^{\circ}$ C and pressure of 1 bar, E° .

$$\operatorname{Zn}(s) + \frac{1}{2}\operatorname{O}_2(g) \to \operatorname{ZnO}(s)$$
 $E^{\circ} = 1.65\,\mathrm{V}$ (8)

B.2 A zinc–air battery was discharged at 20 mA for 24 hours. **CALCULATE** the 3pt change in mass of the negative electrode (anode) in the battery.

5pt

Mt. Fuji

B.3 Consider the change of e.m.f. of a zinc–air battery depending on the environment. **CALCULATE** the e.m.f. at the summit of Mt. Fuji, where the temperature and altitude are $-38\,^{\circ}\text{C}$ (February) and 3776 m, respectively. The atmospheric pressure is represented by equation 9 below at altitude h [m] and temperature T [$^{\circ}\text{C}$].

$$P\left[\mathsf{bar}\right] = 1.013 \times \left(1 - \frac{0.0065h}{T + 0.0065h + 273.15}\right)^{5.257} \tag{9}$$

The molar ratio of oxygen in the atmosphere is 21%. The Gibbs energy change of reaction (8) is $\Delta G_{\rm ZnO}(-38\,^{\circ}{\rm C})=-3.26\times10^2\,{\rm kJ\,mol^{-1}}$ at $-38\,^{\circ}{\rm C}$ and 1 bar.

B.4 CALCULATE the Gibbs energy change for reaction (6) at $25\,^{\circ}$ C. Note that the standard reduction potentials, $E^{\circ}(Zn^{2+}/Zn)$ and $E^{\circ}(O_2/H_2O)$ at $25\,^{\circ}$ C and 1 bar are given as (10) and (11), respectively.

$$Zn^{2+} + 2e^{-} \rightarrow Zn$$
 $E^{\circ}(Zn^{2+}/Zn) = -0.77 V$ (10)

$$O_2 + 4H^+ + 4e^- \rightarrow 2H_2O$$
 $E^{\circ}(O_2/H_2O) = 1.23V$ (11)

Question	A.1	A.2	A.3	A.4	B.1	B.2	B.3	Total
Points	9	7	6	10	5	15	8	60
Score								

Although silicon is also a group 14 element like carbon, their properties differ significantly.

Part A

Unlike the carbon–carbon triple bond, the silicon–silicon triple bond in a written as R^1 –Si \equiv Si– R^1 (R: organic substituent), is extremely reactive. For example, it reacts with ethylene to form a cyclic product that contains a four-membered ring.

$$R^1-Si\equiv Si-R^1+H_2C=CH_2$$

$$\longrightarrow Si=Si$$

$$R^1$$

$$R^1$$

When $R^1-Si \equiv Si-R^1$ is treated with an alkyne ($R^2-C \equiv C-R^2$), the four-membered-ring compound ${\bf A}$ is formed as an initial intermediate. Further reaction of another molecule of $R^2-C \equiv C-R^2$ with ${\bf A}$ affords isomers ${\bf B}$ and ${\bf C}$, both of which have cyclic, benzene-like conjugated structures, so-called 'disilabenzenes' that contain a six-membered ring and can be written as $(R^1-Si)_2(R^2-C)_4$.

$$R^1-Si\equiv Si-R^1+R^2-C\equiv C-R^2$$
 \longrightarrow A $\xrightarrow{R^2-C\equiv C-R^2}$ B + C

The 13 C NMR analysis of the corresponding six-membered ring skeletons Si_2C_4 shows two signals for **B** and one signal for **C**.

A.1 DRAW the structures of **A**, **B**, and **C** using R¹, R², Si, and C. (Only one resonance 9pt structure is needed, if applicable.)

A.2 CALCULATE the aromatic stabilization energy (ASE) for benzene and compound 7pt C (where $R^1 = R^2 = H$) as positive values. The enthalpy change of some hydrogenation reactions of unsaturated systems is shown below (Figure 1).

Figure 1.

When a xylene solution of **C** is heated, it undergoes isomerization to give an equilibrium mixture of compounds **D** and **E**. The mole ratio is **D** : **E** = 1 : 40.0 at 50.0 $^{\circ}$ C, and **D** : **E** = 1 : 20.0 at 120.0 $^{\circ}$ C.

A.3 CALCULATE ΔH for the transformation of **D** to **E**. Assume that ΔH does not depend on temperature.

The isomerization from **C** to **D** and **D** to **E** proceeds via transformations of π -bonds into σ -bonds without breaking any σ -bonds. A ¹³C NMR analysis revealed one signal for the Si₂C₄ skeleton of **D** and two signals for that of **E**. The skeleton of **D** does not contain any three-membered rings, while **E** has two three-membered rings that share an edge.

A.4 DRAW the structures of **D** and **E** using R¹, R², Si, and C.

10pt

Part B

Silicon is able to form highly coordinated compounds (> four substituents) with electronegative elements such as fluorine. Metal fluorides are often used as fluorination reagents and highly coordinated silicon fluorides also act as fluorination reagents.

The fluorination reaction of CCl₄ using Na₂SiF₆ was carried out as follows.

Standardization of Na₂SiF₆ solution :

Preparation

- Aqueous solution **F**: 0.855 g of Na_2SiF_6 (188.053 g mol⁻¹) dissolved in water (total volume: 200 mL).
- Aqueous solution **G**: 6.86 g of $Ce_2(SO_4)_3$ (568.424 g mol⁻¹) dissolved in water (total volume: 200 mL).

Procedure

• Precipitation titration of a solution **F** (50.0 mL) by dropwise adding solution **G** in the presence of xylenol orange, which coordinates to Ce^{3+} , as an indicator. After adding 18.8 mL of solution **G**, the color of the solution changes from yellow to magenta. The generated precipitate is a binary compound that contains Ce^{3+} , and the only resulting silicon compound is $Si(OH)_4$.

B.1 WRITE the balanced equation for the reaction of Na_2SiF_6 with $Ce_2(SO_4)_3$.

5pt

Reaction of CCl₄with Na₂SiF₆:

(Substance losses, e.g. by evaporation, are negligible during the following steps.)

• Na₂SiF₆(x [g]) was added to CCl₄ (500.0 g) and heated to 300°C in a sealed, pressure-resistant reaction vessel. The unreacted Na₂SiF₆ and generated NaCl were removed by filtration. The filtrate was diluted to a total volume of 1.00 L with CCl₄ (solution H). The ²⁹Si and ¹⁹F NMR spectra of solution H showed SiF₄ as the only silicon compound. In the ¹⁹F NMR spectrum, in addition to SiF₄, signals corresponding to CFCl₃, CF₂Cl₂, CF₃Cl, and CF₄ were observed (*cf.* Table 1). The integration ratios in the ¹⁹F NMR spectrum are proportional to the number of fluorine nuclei.

Table 1

¹⁹ F NMR data	CFCl ₃	CF ₂ Cl ₂	CF ₃ Cl	CF ₄
Integration ratio	45.0	65.0	18.0	2.0

SiF₄ is hydrolyzed to form H₂SiF₆ according to the following equation:

$$3SiF_4 + 2H_2O \rightarrow SiO_2 + 2H_2SiF_6$$
 (8)

- Solution **H** (10 mL) was added to an excess amount of water, which resulted in the complete hydrolysis of SiF₄. After separation, the H₂SiF₆ generated from the hydrolysis in the aqueous solution was neutralized and completely converted to Na₂SiF₆ (aqueous solution **J**).
- The precipitate of unreacted Na₂SiF₆ and NaCl, which was removed by filtration in the initial step (underlined above), was completely dissolved in water to give an aqueous solution (solution K; 10.0 L).
- Then, additional precipitation titrations using solution **G** were carried out. The entire amount of solution **J** required 61.6 mL of titrant to reach the endpoint. Separately, 100 mL of solution **K** used 44.4 mL of titrant to reach the endpoint. It should be noted here that the coexistence of NaCl or SiO₂ has no effect on the precipitation titration.
- **B.2 CALCULATE** the mass of the NaCl produced in the reaction vessel (underlined above), and **CALCULATE** the mass (x [g]) of the Na₂SiF₆ used as a starting material.
- **B.3** 77.8% of the CCl_4 used as a starting material was unreacted. **CALCULATE** the 8pt mass of CF_3Cl generated.

Volcano at Sakurajima island

Part A

Japan is one of the countries with the largest number of volcanos worldwide. When silicate minerals crystallize from magma, some of the transition-metal ions (M^{n+}) in the magma are incorporated into the silicate minerals. The M^{n+} studied in this problem are coordinated by oxide ions (O^{2-}) and adopt a four-coordinate tetrahedral (T_{d}) geometry in the magma. In the silicate minerals, the ions form six-coordinate octahedral (O_{h}) geometry. Both types of complexes exhibit a high-spin electron configuration. The distribution coefficient of M^{n+} between the silicate minerals and magma, D, can be expressed by:

$$D = \frac{[\mathrm{M}]_{\mathrm{s}}}{[\mathrm{M}]_{\mathrm{l}}}$$

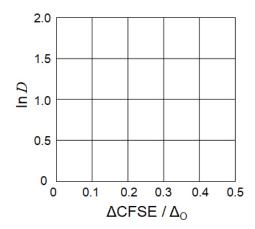

where $[M]_s$ and $[M]_l$ are the concentrations of M^{n+} in the silicate minerals and the magma, respectively. The table below shows the D values of Cr^{2+} and Mn^{2+} as examples.

	Cr ²⁺	Mn ²⁺
\overline{D}	7.2	1.1

 Δ_O is the energy separation of the d-orbitals of M^{n+} , and CFSE^O is the crystal-field stabilization energy in a O_h field. Let Δ_T and CFSE^T be those in a T_d field.

- **A.1 CALCULATE** Δ CFSE, defined as $|CFSE^O CFSE^T|$ in terms of Δ_O for Cr^{2+} , Mn^{2+} , 6pt and Co^{2+} ; assume $\Delta_T = 4/9\Delta_O$.
- A.2 A linear relationship is observed by plotting $\ln D$ against $\Delta \text{CFSE} / \Delta_0$ in the Cartesian coordinate system shown below. **CALCULATE** the approximate value of D for Co^{2+} .

Metal oxides MO (M: Ca, Ti, V, Mn, or Co) crystallize in a rock-salt structure wherein the M^{n+} adopts an O_h geometry with a high-spin electron configuration. The lattice enthalpy of these oxides is primarily determined by the Coulombic interactions (due to the radius and charge of the ions) with some contribution from the CFSE of M^{n+} in the O_h field.

A.3 CHOOSE the appropriate set of lattice enthalpies $[k] \text{ mol}^{-1}]$ from one of the options (a) to (f).

	CaO	TiO	VO	MnO	CoO
(a)	3460	3878	3913	3810	3916
(b)	3460	3916	3878	3810	3913
(c)	3460	3913	3916	3810	3878
(d)	3810	3878	3913	3460	3916
(e)	3810	3916	3878	3460	3913
(f)	3810	3913	3916	3460	3878

Part B

A mixed oxide **A**, containing La³⁺ and Cu²⁺, crystallizes in a tetragonal unit cell shown in Figure 1. In the $[CuO_6]$ octahedron, the Cu–O length along the z-axis (l_z) is longer than that of the x-axis (l_x), and $[CuO_6]$ is distorted from the regular O_h geometry. This distortion removes the degeneracy of the e_g orbitals ($d_{x^2-y^2}$ and d_{z^2}).

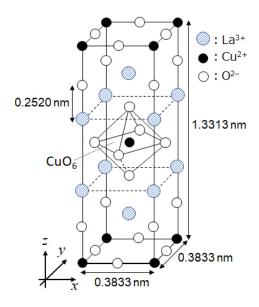

Figure 1.

A can be synthesized by thermal decomposition (pyrolysis) of complex **B**, which is formed by mixing metal chlorides in dilute aqueous ammonia solution containing squaric acid ($C_4H_2O_4$), a diacid. Upon pyrolysis in dry air to 200 °C, **B** loses 29.1% of its mass due to the loss of crystallization water. Another weight loss is observed when heating is continued to 700 °C due to the release of CO_2 . The total weight loss during the formation of **A** from **B** is 63.6%. It should be noted that only water and CO_2 are released in the pyrolysis reaction.

B.1	WRITE the chemical formula for A and B .	6pt
B.2	CALCULATE l_x and l_z using Figure 1.	4pt
В.3	For Cu^{2+} in the distorted $[CuO_6]$ octahedron in A of Figure 1, WRITE the names of the split e_g orbitals $(d_{x^2-y^2}$ and $d_{z^2})$ on lines (i) and (ii), and PLACE electrons on the energy diagram in the dotted box on your answer sheet.	4pt

A is an insulator. One hole is generated in the crystal lattice of **A** when one La³⁺ is substituted with one Sr²⁺. As a result, the Sr²⁺-doped **A** conducts electricity and shows superconductivity below 38 K. When the substitution described takes place in **A**, 2.05×10^{27} holes m⁻³ were generated.

B.4 CALCULATE the percentage of Sr²⁺ substituted for La³⁺ based on the mole ratio in the substitution. Note that the valencies of the constituent ions and the crystal structure are not altered by the substitution.

Part C

 $Cu_2(CH_3CO_2)_4$ is composed of four $CH_3CO_2^-$ coordinated to two Cu^{2+} (Figure 2A). $Cu_2(CH_3CO_2)_4$ exhibits high levels of structural symmetry, with two axes passing through the carbon atoms of the four $CH_3CO_2^-$ and an axis passing through the two Cu^{2+} , all of which are oriented orthogonal relative to each other. When a dicarboxylate ligand is used instead of $CH_3CO_2^-$, a "cage complex" is formed. The cage complex $Cu_4(\mathbf{L1})_4$ is composed of planar dicarboxylate **L1** (Figure 2B) and Cu^{2+} (Figure 2C). The structure of the cage complex is determined by the angle θ between the coordination directions of the two carboxylates, indicated by the arrows in Figure 2B. θ is 0° for **L1**. Hydrogen atoms are not shown in Figure 2.

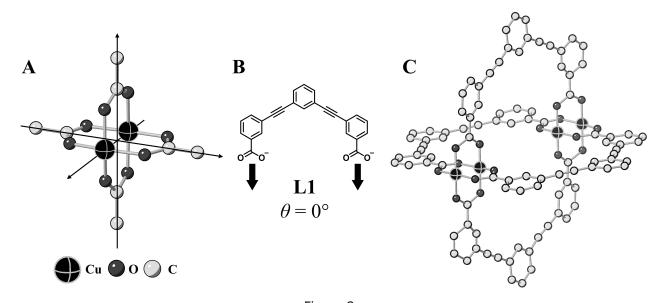

Figure 2.

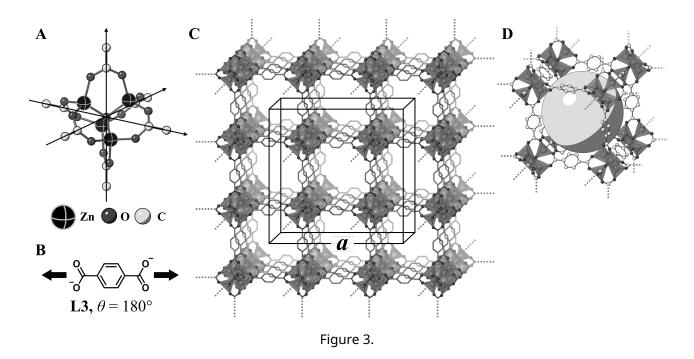

The θ of the planar dicarboxylate **L2** below is fixed to 90°. If the composition 5pt of the cage complex formed from **L2** and Cu^{2+} is $\operatorname{Cu}_n(\mathbf{L2})_m$, **GIVE** the smallest integer combination of n and m. Assume that only the CO_2 groups of **L2** coordinate to Cu^{2+} ions.

L2
$$\theta = 90^{\circ}$$

A zinc complex, $Zn_4O(CH_3CO_2)_6$, contains four tetrahedral Zn^{2+} , six $CH_3CO_2^-$, and one O^{2-} (Figure 3A). In $Zn_4O(CH_3CO_2)_6$, the O^{2-} is located at the origin, and the three axes passing through the carbon atoms of $CH_3CO_2^-$ are oriented orthogonal relative to each other. When p-benzenedicarboxylate (Figure 3B, L3, θ = 180°) is used instead of $CH_3CO_2^-$, the Zn^{2+} clusters are linked to each other to form a crystalline solid (X) that is called a "porous coordination polymer" (Figure 3C). The composition of Z is $[Zn_4O(L3)_3]_n$, and it has a cubic crystal structure with nano-sized pores. One pore is represented as a sphere in Figure 3D, and each tetrahedral Zn^{2+} cluster is represented as a dark gray polyhedron in Figures 3C and 3D. Hydrogen atoms are not shown in Figure 3.

- **C.2 X** has a cubic unit cell with a side length of a (Figure 3C) and a density of 0.592 5pt g cm⁻³. **CALCULATE** a in [cm].
- **C.3 X** contains a considerable number of pores, and 1 g of **X** can accommodate 3.0×10^2 mL of CO₂ gas in the pores at 1 bar and 25 °C. **CALCULATE** the average number of CO₂ molecules per pore.

Polycyclic aromatic hydrocarbons with successive ortho-connections are called [n]carbohelicenes (n represents the number of six-membered rings; see below). [4]Carbohelicene ([4]C) is efficiently prepared according to the synthesis shown below. The key photochemical reaction proceeds via the intermediate (Int.) that is then easily oxidized by iodine.

The photochemical reaction proceeds in a manner similar to the following example.

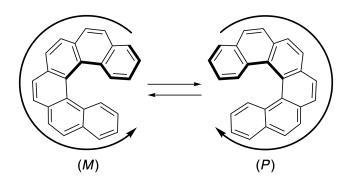

(2H)

USA-3 C-8 Q-2

Note: For all of Question 8, please draw alternating single and double bonds in your answers to the problems as depicted in the examples of carbohelicene. Do not use circles for conjugated π systems.

A.1	DRAW the structures of A-C . Stereoisomers should be distinguished.	9pt
A.2	Attempts to synthesize [5]carbohelicene from the same phosphonium salt and an appropriate starting compound resulted in the formation of only a trace amount of [5]carbohelicene. Instead, product $\bf D$ whose molecular weight was 2 Da lower than that of [5]carbohelicene was isolated. The ¹ H NMR chemical shifts of $\bf D$ are listed below. DRAW the structure of $\bf D$. [$\bf D$ (δ , ppm in CS ₂ , r.t.), 8.85 (2H), 8.23 (2H), 8.07 (2H), 8.01 (2H), 7.97 (2H), 7.91	3pt

[5]- and larger [n]carbohelicenes have helical chirality and interconversion between enantiomers of these helicenes is very slow at room temperature. The chirality of [n]carbohelicenes is defined as (*M*) or (*P*) as shown below.

[n]Carbohelicenes with n larger than 4 can be enantiomerically separated by chiral column chromatography, which was developed by Prof. Yoshio Okamoto.

Multiple helicenes are molecules that contain two or more helicene-like structures. Considering helical chirality, several stereoisomers exist in a multiple helicene. For example, compound $\bf E$ contains three [5]carbohelicene-like moieties in one molecule. One of the stereoisomers is described as (P, P, P) and shown below.

$$(1, 2, 3) = (P, P, P)$$

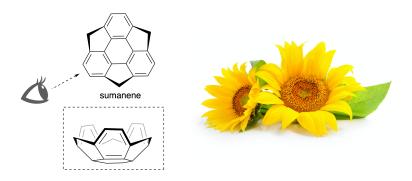

A.3 The nickel-mediated trimerization of 1,2-dibromobenzene generates triphenylene. When the same reaction is applied to an enantiomer of \mathbf{F} , (P)- \mathbf{F} , multiple helicene \mathbf{G} ($C_{66}H_{36}$) is obtained. Interconversion between stereoisomers does not occur during the reaction. **DRAW** one possible stereoisomer of \mathbf{G} with the chirality defined as in the example above, including numerical labels. **LIST ALL** remaining stereoisomers with location numbers and M and P labels according to the same numbering. For instance, the other stereoisomers of \mathbf{E} would be listed as (1, 2, 3) = (P, M, P), (P, M, M), (P, P, M), (M, M, M), (M, M, P), (M, P, P), and (M, P, M).

Part B

Sumanene is a bowl-shaped hydrocarbon that was first reported in Japan in 2003. The name "sumanene" comes from a Sanskrit-Hindi word "suman" that means sunflower. The synthesis of sumanene was originally completed by a reaction sequence consisting of a ring-opening and a ring-closing metathesis.

Representative metathesis reactions, catalyzed by a ruthenium catalyst (Ru*), are shown below.

B.1 DRAW the structure of intermediate **I** (ignore stereochemistry).

B.2 Starting with the optically active precursor J, the same reaction sequence gives the optically active sumanene derivative K. The stereocenters in J are unchanged during the metathesis reaction. DRAW the structure of K with appropriate stereochemistry.

Good kids don't do this, but if you unseam a tennis ball, you can disassemble it into two U-shaped pieces.

Based on this idea, compounds **1** and **2** were synthesized as U-shaped molecules with different sizes. Compound **3** was prepared for comparison to **1**. The encapsulation behavior of these compounds was investigated.

USA (United States of America)

The synthetic route to 2 is shown below. The composition of compound 9 by mass is C: 40.49%, H: 1.70%, and O: 17.98%.

A.1 DRAW the structures of **4–9**; ignore stereochemistry. Use "PMB" as a substituent instead of drawing the whole structure of the *p*-methoxybenzyl group shown in the scheme above.

In the mass spectrum of **1**, the ion peak corresponding to its dimer ($\mathbf{1}_2$) was clearly observed, whereas an ion peak for $\mathbf{3}_2$ was not observed in the spectrum of **3**. In the 1 H NMR spectra of a solution of $\mathbf{1}_2$, all the NH protons were observed to be chemically equivalent. The chemical shift was significantly different from that of the NH protons of **3**. These data indicate that hydrogen bonds are formed between the NH groups of **1** and atoms **X** of another molecule of **1** to form the dimeric capsule.

A.2	CIRCLE all the appropriate atom(s) X in compound 1 .	2pt
A.3	WRITE the number of hydrogen bonds in the dimeric capsule (1_2) .	2pt

The dimeric capsule of $\mathbf{1}$ ($\mathbf{1}_2$) has an internal space where an appropriate small molecule Z can be encapsulated. This phenomenon is expressed by the following equation:

$$\mathsf{Z} + \mathsf{1}_2 \to \mathsf{Z} @ \mathsf{1}_2 \tag{1}$$

The equilibrium constant of the encapsulation of Z into $\mathbf{1}_2$ is given below:

$$K_{\mathsf{a}} = \frac{[\mathsf{Z} @ \mathbf{1}_2]}{[\mathsf{Z}][\mathbf{1}_2]} \tag{2}$$

Encapsulation of a molecule into a capsule could be monitored by NMR spectroscopy. For example, $\mathbf{1}_2$ in C_6D_6 gave different signals in the 1H NMR spectra before and after addition of CH_4 .

Compound **2** also forms a rigid and large dimeric capsule ($\mathbf{2}_2$). The 1H NMR spectrum of $\mathbf{2}_2$ was measured in C_6D_6 , C_6D_5F , and a C_6D_6/C_6D_5F solvent mixture, with all other conditions kept constant. The chemical shifts for the H^a protons of **2** in the solvents given above are summarized below. No other signals due to the H^a protons in **2** were observed (except for those listed). Assume that the interior of the capsule is always filled with the largest possible number of solvent molecules and that each signal corresponds to one species of the filled capsule.

solvent	δ (ppm) of H $^{\rm a}$
C_6D_6	4.60
C ₆ D ₅ F	4.71
C_6D_6 / C_6D_5F	4.60, 4.71, 4.82

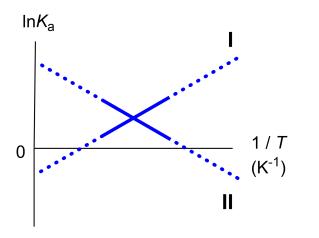

A.4 DETERMINE the number of C_6D_6 and C_6D_5F molecules encapsulated in $\mathbf{2}_2$ giving 3pt each H^a signal.

 1 H NMR measurements in C_6D_6 revealed that $\mathbf{2}_2$ can incorporate one molecule of 1-adamantanecarboxylic acid (AdA), and the association constants (K_a), expressed below, were determined at various temperatures. [solvent@ $\mathbf{2}_2$] denotes a species containing one or more solvent molecules.

$$K_{\mathsf{a}} = \frac{[\mathsf{Z}@\mathbf{2}_2]}{[\mathsf{Z}][\mathsf{solvent}@\mathbf{2}_2]} \tag{3}$$

Similarly, $K_{\rm a}$ values of CH₄ and ${\bf 1}_2$ (equation 2) at various temperatures in C₆D₆ were also determined by $^1{\rm H}$ NMR measurements. The plots of the two association constants (as $\ln K_{\rm a}$ vs 1/T) are shown below.

A.5 WRITE the correct letter, A or B, to fill in (1)–(5) in the following paragraph. No C_6D_6 molecule is encapsulated in $\mathbf{1}_2$. In line **II**, the entropy change (ΔS) is (1) and enthalpy change (ΔH) is (2), indicating that the driving force for the encapsulation in line **II** is (3). Therefore, line **I** corresponds to (4), and line **II** corresponds to (5).

	A	В
(1)	positive	negative
(2)	positive	negative
(3)	ΔS	ΔH
(4)	1_2 and CH_4	2_2 and AdA
(5)	1_2 and CH_4	2_2 and AdA
